IPCO X, New York, June 2004

## Introduction

- Consider a 0-1 ILP of the form

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

## Introduction

- Consider a 0-1 ILP of the form

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by a set of "conditional" linear constraints involving additional continuous variables $y$

## Introduction

- Consider a 0-1 ILP of the form

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by a set of "conditional" linear constraints involving additional continuous variables $y$

$$
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i} \quad \text { for all } i \in I
$$

## Introduction

- Consider a 0-1 ILP of the form

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by a set of "conditional" linear constraints involving additional continuous variables $y$

$$
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i} \quad \text { for all } i \in I
$$

plus a (possibly empty) set of "unconditional" linear constraints on the continuous variables $y$

$$
D y \geq e
$$

## Introduction

- Consider a 0-1 ILP of the form

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by a set of "conditional" linear constraints involving additional continuous variables $y$

$$
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i} \quad \text { for all } i \in I
$$

plus a (possibly empty) set of "unconditional" linear constraints on the continuous variables $y$

$$
D y \geq e
$$

- Note: the continuous variables $y$ do not appear in the objective function-they are only introduced to force some feasibility properties of the $x$ 's.

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$
- conditional constraints are the logical implications:

$$
x_{i j}=1 \Rightarrow y_{j} \geq y_{i}+\text { travel_time }(i, j)
$$

- unconditional constraints limit the arrival time at each city $i$ :

$$
\text { early_arrival_time }(i) \leq y_{i} \leq \text { late_arrival_time }(i) .
$$

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$
- conditional constraints are the logical implications:

$$
x_{i j}=1 \Rightarrow y_{j} \geq y_{i}+\text { travel_time }(i, j)
$$

- unconditional constraints limit the arrival time at each city $i$ :

$$
\text { early_arrival_time }(i) \leq y_{i} \leq \text { late_arrival_time }(i) .
$$

- Map Labelling Problem: placing as many rectangular labels as possible (without overlap) in a given 2-dimensional map

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$
- conditional constraints are the logical implications:

$$
x_{i j}=1 \Rightarrow y_{j} \geq y_{i}+\text { travel_time }(i, j)
$$

- unconditional constraints limit the arrival time at each city $i$ :

$$
\text { early_arrival_time }(i) \leq y_{i} \leq \text { late_arrival_time }(i) .
$$

- Map Labelling Problem: placing as many rectangular labels as possible (without overlap) in a given 2-dimensional map
- binary variables are associated to the relative position of the pairs of labels to be placed

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$
- conditional constraints are the logical implications:

$$
x_{i j}=1 \Rightarrow y_{j} \geq y_{i}+\text { travel_time }(i, j)
$$

- unconditional constraints limit the arrival time at each city $i$ :

$$
\text { early_arrival_time }(i) \leq y_{i} \leq \text { late_arrival_time }(i) .
$$

- Map Labelling Problem: placing as many rectangular labels as possible (without overlap) in a given 2-dimensional map
- binary variables are associated to the relative position of the pairs of labels to be placed
- continuous variables give the placement coordinates of the labels

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$
- conditional constraints are the logical implications:

$$
x_{i j}=1 \Rightarrow y_{j} \geq y_{i}+\text { travel_time }(i, j)
$$

- unconditional constraints limit the arrival time at each city $i$ :

$$
\text { early_arrival_time }(i) \leq y_{i} \leq \text { late_arrival_time }(i) .
$$

- Map Labelling Problem: placing as many rectangular labels as possible (without overlap) in a given 2-dimensional map
- binary variables are associated to the relative position of the pairs of labels to be placed
- continuous variables give the placement coordinates of the labels
- conditional constraints are of the type "if label $i$ is placed on the right of label $j$, then the horizontal coordinates of $i$ and $j$ must obey a certain linear inequality giving a suitable separation condition"

## Examples

- Asymmetric Travelling Salesman Problem with Time Windows
- binary variables $x_{i j}=$ usual arc variables
- continuous variables $y_{i}=$ arrival time at city $i$
- conditional constraints are the logical implications:

$$
x_{i j}=1 \Rightarrow y_{j} \geq y_{i}+\text { travel_time }(i, j)
$$

- unconditional constraints limit the arrival time at each city $i$ :

$$
\text { early_arrival_time }(i) \leq y_{i} \leq \text { late_arrival_time }(i) .
$$

- Map Labelling Problem: placing as many rectangular labels as possible (without overlap) in a given 2-dimensional map
- binary variables are associated to the relative position of the pairs of labels to be placed
- continuous variables give the placement coordinates of the labels
- conditional constraints are of the type "if label $i$ is placed on the right of label $j$, then the horizontal coordinates of $i$ and $j$ must obey a certain linear inequality giving a suitable separation condition"
- unconditional constraints limit the label coordinates

## The (in)famous big- $M$ method

- Conditional constraints

$$
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i} \quad \text { for all } i \in I
$$

typically modeled as follows (for sufficiently large $M_{i}>0$ ):

$$
a_{i}^{T} y \geq b_{i}-M_{i}\left(1-x_{j(i)}\right) \quad \text { for all } i \in I
$$

## The (in)famous big-M method

- Conditional constraints

$$
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i} \quad \text { for all } i \in I
$$

typically modeled as follows (for sufficiently large $M_{i}>0$ ):

$$
a_{i}^{T} y \geq b_{i}-M_{i}\left(1-x_{j(i)}\right) \quad \text { for all } i \in I
$$

- Drawbacks:
- Very poor LP relaxation
- Large mixed-integer model involving both $x$ and $y$ variables

The MIP solver is "carrying on its shoulders" the burden of all additional constraints and variables at all branch-decision nodes, while these become relevant only when the corresponding $x_{j(i)}$ attain value 1 (typically, because of branching).

## The (in)famous big-M method

- Conditional constraints

$$
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i} \quad \text { for all } i \in I
$$

typically modeled as follows (for sufficiently large $M_{i}>0$ ):

$$
a_{i}^{T} y \geq b_{i}-M_{i}\left(1-x_{j(i)}\right) \quad \text { for all } i \in I
$$

- Drawbacks:
- Very poor LP relaxation
- Large mixed-integer model involving both $x$ and $y$ variables

The MIP solver is "carrying on its shoulders" the burden of all additional constraints and variables at all branch-decision nodes, while these become relevant only when the corresponding $x_{j(i)}$ attain value 1 (typically, because of branching).

- Note: one can get rid of the $y$ variables by using Benders' decomposition, but this just a way to speed-up the LP solution-the resulting cuts are weak and still depend on the big-M values.

# Combinatorial Benders' cuts 

$$
\begin{gathered}
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i}, \text { for all } i \in I \\
D y \geq e
\end{gathered}
$$

## Combinatorial Benders' cuts

$$
\begin{gathered}
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i}, \text { for all } i \in I \\
D y \geq e
\end{gathered}
$$

- We work on the space of the $x$-variables only, as in the classical Benders's approach, but ...

## Combinatorial Benders' cuts

$$
\begin{gathered}
x_{j(i)}=1 \Rightarrow a_{i}^{T} y \geq b_{i}, \text { for all } i \in I \\
D y \geq e
\end{gathered}
$$

- We work on the space of the $x$-variables only, as in the classical Benders's approach, but ...
- ... we model the constraints involving the $y$ variables through the following Combinatorial Benders' (CB) cuts:

$$
\sum_{i \in C} x_{j(i)} \leq|C|-1
$$

where $C \subseteq I$ is an inclusion-minimal set such that the linear system

$$
S L A V E(C):=\left\{\begin{array}{c}
a_{i}^{T} y \geq b_{i}, \text { for all } i \in C \\
D y \geq e
\end{array}\right.
$$

has no feasible (continuous) solution $y$.

## CB cut separation

- CB cut violated by a given $x^{*} \in[0,1]^{n}$ iff $\sum_{i \in C}\left(1-x_{j(i)}^{*}\right)<1$, hence;
(i) weigh each conditional constraint $a_{i}^{T} y \leq b_{i}$ by $1-x_{j(i)}^{*}$;
(ii) weigh each unconditional constraint in $D y \geq e$ by 0 ;
(iii) look for a minimum-weight MIS (minimal infeasible system, or IIS) of the resulting weighted system (NP-hard).

## CB cut separation

- CB cut violated by a given $x^{*} \in[0,1]^{n}$ iff $\sum_{i \in C}\left(1-x_{j(i)}^{*}\right)<1$, hence;
(i) weigh each conditional constraint $a_{i}^{T} y \leq b_{i}$ by $1-x_{j(i)}^{*}$;
(ii) weigh each unconditional constraint in $D y \geq e$ by 0 ;
(iii) look for a minimum-weight MIS (minimal infeasible system, or IIS) of the resulting weighted system (NP-hard).
- A simple polynomial-time heuristic:
- start with $C:=\left\{i \in I: x_{j(i)}^{*}=1\right\}$,
- verify the infeasibility of

$$
S L A V E(C):=\left\{\begin{array}{c}
a_{i}^{T} y \geq b_{i}, \text { for all } i \in C \\
D y \geq e
\end{array}\right.
$$

by classical LP tools,

- make $C$ inclusion-minimal in a greedy way.

## CB cut separation

- CB cut violated by a given $x^{*} \in[0,1]^{n}$ iff $\sum_{i \in C}\left(1-x_{j(i)}^{*}\right)<1$, hence;
(i) weigh each conditional constraint $a_{i}^{T} y \leq b_{i}$ by $1-x_{j(i)}^{*}$;
(ii) weigh each unconditional constraint in $D y \geq e$ by 0 ;
(iii) look for a minimum-weight MIS (minimal infeasible system, or IIS) of the resulting weighted system (NP-hard).
- A simple polynomial-time heuristic:
- start with $C:=\left\{i \in I: x_{j(i)}^{*}=1\right\}$,
- verify the infeasibility of

$$
S L A V E(C):=\left\{\begin{array}{c}
a_{i}^{T} y \geq b_{i}, \text { for all } i \in C \\
D y \geq e
\end{array}\right.
$$

by classical LP tools,

- make $C$ inclusion-minimal in a greedy way.
- The above heuristic is indeed exact when $x^{*}$ is integer.

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far
2. apply the CB separation heuristic so as to generate new violated combinatorial cuts-and to assert the feasibility of $x^{*}$, if integer.

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far
2. apply the CB separation heuristic so as to generate new violated combinatorial cuts-and to assert the feasibility of $x^{*}$, if integer.

## Notes:

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far
2. apply the CB separation heuristic so as to generate new violated combinatorial cuts-and to assert the feasibility of $x^{*}$, if integer.

## Notes:

- The generated CB cuts automatically distill combinatorial information hidden in the MIP model, triggering the activation of other classes of combinatorial cuts, including Caprara-Fischetti $\{0,1 / 2\}$-cuts.

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far
2. apply the CB separation heuristic so as to generate new violated combinatorial cuts-and to assert the feasibility of $x^{*}$, if integer.

## Notes:

- The generated CB cuts automatically distill combinatorial information hidden in the MIP model, triggering the activation of other classes of combinatorial cuts, including Caprara-Fischetti $\{0,1 / 2\}$-cuts.
- The role of the big-M terms in the MIP model vanishes-only logical implications are relevant, no matter the way they are modelled $\Rightarrow$ logical implications can be stated explicitly in the model.

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far
2. apply the CB separation heuristic so as to generate new violated combinatorial cuts-and to assert the feasibility of $x^{*}$, if integer.

## Notes:

- The generated CB cuts automatically distill combinatorial information hidden in the MIP model, triggering the activation of other classes of combinatorial cuts, including Caprara-Fischetti $\{0,1 / 2\}$-cuts.
- The role of the big-M terms in the MIP model vanishes-only logical implications are relevant, no matter the way they are modelled $\Rightarrow$ logical implications can be stated explicitly in the model.
- Related to the concept of nogoods (minimal infeasible configurations of the binary variables) used in Constraint Programming (Hooker and Ottosson, 2003, and Thorsteinsson, 2001).

## A Branch\&Cut solution scheme

- Work in the $x$ space. At each branching node:

1. solve the LP relaxation of the Master Problem

$$
\min \left\{c^{T} x: F x \leq g, x \in\{0,1\}^{n}\right\}
$$

amended by the CB cuts generated so far
2. apply the CB separation heuristic so as to generate new violated combinatorial cuts-and to assert the feasibility of $x^{*}$, if integer.

## Notes:

- The generated CB cuts automatically distill combinatorial information hidden in the MIP model, triggering the activation of other classes of combinatorial cuts, including Caprara-Fischetti $\{0,1 / 2\}$-cuts.
- The role of the big-M terms in the MIP model vanishes-only logical implications are relevant, no matter the way they are modelled $\Rightarrow$ logical implications can be stated explicitly in the model.
- Related to the concept of nogoods (minimal infeasible configurations of the binary variables) used in Constraint Programming (Hooker and Ottosson, 2003, and Thorsteinsson, 2001).
- Interesting connections with Chvátal's resolution search and with Glover-Tangedhal's dynamic branch and bound.

## A more general framework

- Consider a MIP problem with the following structure:

$$
\begin{align*}
z^{*}:=\min & c^{T} x+0^{T} y  \tag{1}\\
\text { s.t. } & F x \leq g  \tag{2}\\
& M x+A y \geq b  \tag{3}\\
& D y \geq e  \tag{4}\\
& x_{j} \in\{0,1\} \quad \text { for } j \in B \tag{5}
\end{align*}
$$

## A more general framework

- Consider a MIP problem with the following structure:

$$
\begin{align*}
z^{*}:=\min & c^{T} x+0^{T} y  \tag{1}\\
\text { s.t. } & F x \leq g  \tag{2}\\
& M x+A y \geq b  \tag{3}\\
& D y \geq e  \tag{4}\\
& x_{j} \in\{0,1\} \quad \text { for } j \in B \tag{5}
\end{align*}
$$

- We assume linking constraints (3) are of the type:

$$
\begin{equation*}
m_{i, j(i)} x_{j(i)}+a_{i}^{T} y \geq b_{i} \text { for all } i \in I \tag{6}
\end{equation*}
$$

## A more general framework

- Consider a MIP problem with the following structure:

$$
\begin{align*}
z^{*}:=\min & c^{T} x+0^{T} y  \tag{1}\\
\text { s.t. } & F x \leq g  \tag{2}\\
& M x+A y \geq b  \tag{3}\\
& D y \geq e  \tag{4}\\
& x_{j} \in\{0,1\} \quad \text { for } j \in B \tag{5}
\end{align*}
$$

- We assume linking constraints (3) are of the type:

$$
\begin{equation*}
m_{i, j(i)} x_{j(i)}+a_{i}^{T} y \geq b_{i} \text { for all } i \in I \tag{6}
\end{equation*}
$$

- A useful trick: introduce a continuous copy $x_{j}^{c}$ of each binary variable $x_{j}, j \in B$, and link the two copies through the constraints:

$$
\begin{equation*}
x_{j}=x_{j}^{c} \quad \text { for } j \in B \tag{7}
\end{equation*}
$$

## Master-slave solution scheme

- MASTER:

$$
\begin{array}{cc}
z^{*}=\min & c^{T} x \\
\text { s.t. } & F x \leq g \quad \text { (plus additional cuts, if any) } \\
& x_{j} \in\{0,1\} \text { for } j \in B
\end{array}
$$

## Master-slave solution scheme

- MASTER:

$$
\begin{array}{cc}
z^{*}=\min & c^{T} x \\
\text { s.t. } & F x \leq g \quad \text { (plus additional cuts, if any) } \\
& x_{j} \in\{0,1\} \text { for } j \in B
\end{array}
$$

- $\operatorname{SLAVE}(x)$, a linear system parametrized by $x$ :

$$
\begin{gather*}
A y \geq b-M x  \tag{11}\\
D y \geq e \tag{12}
\end{gather*}
$$

## Master-slave solution scheme

- MASTER:

$$
\begin{array}{cc}
z^{*}=\min & c^{T} x \\
\text { s.t. } & F x \leq g \quad \text { (plus additional cuts, if any) } \\
& x_{j} \in\{0,1\} \text { for } j \in B \tag{10}
\end{array}
$$

- SLAVE $(x)$, a linear system parametrized by $x$ :

$$
\begin{gather*}
A y \geq b-M x  \tag{11}\\
D y \geq e \tag{12}
\end{gather*}
$$

- If $x^{*}$ integer and $S L A V E\left(x^{*}\right)$ infeasible, take any MIS of $\operatorname{SLAVE}\left(x^{*}\right)$ involving the rows of $A$ indexed by $C$ (say)

## Master-slave solution scheme

- MASTER:

$$
\begin{array}{cc}
z^{*}=\min & c^{T} x \\
\text { s.t. } & F x \leq g \quad \text { (plus additional cuts, if any) } \\
& x_{j} \in\{0,1\} \text { for } j \in B \tag{10}
\end{array}
$$

- SLAVE $(x)$, a linear system parametrized by $x$ :

$$
\begin{gather*}
A y \geq b-M x  \tag{11}\\
D y \geq e \tag{12}
\end{gather*}
$$

- If $x^{*}$ integer and $S L A V E\left(x^{*}\right)$ infeasible, take any MIS of $\operatorname{SLAVE}\left(x^{*}\right)$ involving the rows of $A$ indexed by $C$ (say) $\Rightarrow$ at least one binary variable $x_{j(i)}, i \in C$, has to be changed in order to break the infeasibility

## Master-slave solution scheme

- MASTER:

$$
\begin{array}{cc}
z^{*}=\min & c^{T} x \\
\text { s.t. } & F x \leq g \quad \text { (plus additional cuts, if any) } \\
& x_{j} \in\{0,1\} \text { for } j \in B \tag{10}
\end{array}
$$

- $\operatorname{SLAVE}(x)$, a linear system parametrized by $x$ :

$$
\begin{gather*}
A y \geq b-M x  \tag{11}\\
D y \geq e \tag{12}
\end{gather*}
$$

- If $x^{*}$ integer and $S L A V E\left(x^{*}\right)$ infeasible, take any MIS of $\operatorname{SLAVE}\left(x^{*}\right)$ involving the rows of $A$ indexed by $C$ (say) $\Rightarrow$ at least one binary variable $x_{j(i)}, i \in C$, has to be changed in order to break the infeasibility $\Rightarrow$ Combinatorial Benders' (CB) cut:

$$
\begin{equation*}
\sum_{i \in C: x_{j(i)}^{*}=0} x_{j}+\sum_{i \in C: x_{j(i)}^{*}=1}\left(1-x_{j}\right) \geq 1 \tag{13}
\end{equation*}
$$

## Computational Results

- Implementation in C++ embedded within the ILOG-Cplex Concert Technology 1.2 framework (ILOG-Cplex 8.1 MIP solver).
- Experiments on a PC AMD Athlon $2100+$ with 1 GByte RAM, with a time-limit of 3 CPU hours for each run.

## Computational Results

- Implementation in C++ embedded within the ILOG-Cplex Concert Technology 1.2 framework (ILOG-Cplex 8.1 MIP solver).
- Experiments on a PC AMD Athlon $2100+$ with 1 GByte RAM, with a time-limit of 3 CPU hours for each run.
- The test-bed:

1. Map Labelling (max. problem): placing as many rectangular labels as possible (without overlap) in a given map (Mützel and Klau, 2003)
2. Two-Group Statistical Classification (discriminant analysis): given a population whose members can be divided into two distinct classes, define a linear function of some available measures so as to decide whether a new member belongs to the first or second class (Rubin, 1997).

## Computational Results

- Implementation in C++ embedded within the ILOG-Cplex Concert Technology 1.2 framework (ILOG-Cplex 8.1 MIP solver).
- Experiments on a PC AMD Athlon $2100+$ with 1 GByte RAM, with a time-limit of 3 CPU hours for each run.
- The test-bed:

1. Map Labelling (max. problem): placing as many rectangular labels as possible (without overlap) in a given map (Mützel and Klau, 2003)
2. Two-Group Statistical Classification (discriminant analysis): given a population whose members can be divided into two distinct classes, define a linear function of some available measures so as to decide whether a new member belongs to the first or second class (Rubin, 1997).

- All instances have been processed twice:

Cplex: the original MIP model is solved through the commercial ILOG-Cplex 8.1 solver (with default settings), and

CBC: the master/slave reformulation is solved by using $C B$ cuts and $\{0,1 / 2\}$-cuts (still using the ILOG-Cplex 8.1 library).
