What do you actually mean by **"Benders decomposition"?**

- The original Benders decomposition from the '60s uses **two** distinct ingredients for solving a Mixed-Integer Linear Program (MILP):
 - esearch, mathematica 1) A search strategy where a relaxed (NP-hard) MILP on a variable subspace is solved exactly (i.e., to **integrality**) by a black-box solver, and then is iteratively tightened by means of additional "Benders" linear cuts

^{Jacques} F. Benders

- 2) The **technicality** of how to actually compute those cuts (Farkas' projection)
- Papers proposing "a new Benders-like scheme" typically refer to 1)
- Students scared by "Benders implementations" typically refer to 2)

Later developments in the '70s:

- Folklore (Miliotios for TSP?): generate Benders cuts within a **single B&B tree** to cut any infeasible integer solution that is going to update the incumbent
- McDaniel & Devine (1977): use Benders cuts to cut fractional sol.s as well (root node only)
- Everything fits very naturally within a modern **Branch-and-Cut** (B&C) framework. ۲ Lunteren Conference on the Mathematics of Operations Research, January 17, 2017 2

B&C for Mixed-Integer Programming

• We will focus on the MIP

where *f* and *g* are **convex functions**

 $\min f(x, y)$ $g(x, y) \le 0$ Ay < b

y integer

- Non-convexity only comes from integrality requirement on *y*, so it can be handled by a branch-and-bound scheme (possibly using on-thefly cutting planes) → Branch and Cut (B&C) solution scheme
- B&C was proposed by Padberg and Rinaldi in the '90s (i.e., well after Benders seminal work) and is nowadays the method of choice for solving MIP

• This talk: rephrase Benders in "modern slang" #BendersIsEasy

Modern B&C implementation

- Modern commercial B&C solvers such as IBM ILOG Cplex, Gurobi etc. can be fully customized by using callback functions
- Callback functions are just entry points in the B&C code where an advanced user (you!) can add his/her customizations

- Most-used callbacks (using Cplex's jargon)
 - Lazy constraint: add "lazy constr.s" that should be part of the original model
 - User cut: add additional contr.s that hopefully help enforcing feasibility/integrality
 - Heuristic: try to improve the incumbent (primal solution) as soon as possible
 - Branch: modify the branching strategy
 - ...

Lazy constraint callback

- Automatically invoked when a solution is going to update the incumbent (meaning it is integer and feasible w.r.t. current model)
- This is the **last checkpoint** where we can discard a solution for whatever reason (e.g., because it violates a constraint that is not part of the current model)

- To avoid be bothered by this solution again and again, we can/should return a violated constraint (cut) that is added (globally or locally) to the current model
- Cut generation is often simplified by the fact that the solution to be cut is known to be integer (e.g., SECs for TSP)

User cut callback

- Automatically invoked at every B&B node when the current solution is **not integer** (say: just before branching)
- A violated cut can possibly be returned, to be added (locally or globally) to the current model → often leads to an improved convergence to integer solutions
- If no cut is returned, **branching** occurs as usual

- Cut generation **can be hard** as the point is not integer (heuristic approaches can be used)
- User cuts are not mandatory for B&C correctness → being too clever on them can actually slow-down the solver because of the overhead in generating and using them (larger/denser LPs etc.)

Modern Benders

• Consider again the convex MINLP in the (x,y) space

 $\min f(x, y)$ $g(x, y) \le 0$ $Ay \le b$

y integer

and assume for the sake of simplicity that $S := \{y : Ay \le b\}$ is nonempty and bounded, and that

$$X(y) := \{ x : g(x, y) \le 0 \}$$

is **nonempty**, closed and bounded for all $y \in S$

→ the convex function $\Phi(y) := \min_{x \in X(y)} f(x, y)$ is well defined for all $y \in S$

→ no "feasibility cuts" needed (this kind of cuts will be discussed later on) Lunteren Conference on the Mathematics of Operations Research, January 17, 2017

(3)

Life of P(H)I

- Solving Benders' master problem calls for the minimization of a nonlinear convex function (even if you start from a linear problem!)
- Branch-and-cut MINLP solvers generate a sequence of linear cuts to approximate this function from below (outer-approximation)

s.t. $w \ge \Phi(y)$ $Ay \le b$ y integer

Benders cut computation

• Benders (for linear) and Geoffrion (general convex) told us how to compute a (sub)gradient to be used in the cut derivation, by using the optimal primal-dual solution (x^*,u^*) available after computing $\Phi(y^*)$

$$\xi(y^*) = \nabla_y f(x^*, y^*) + u^* \nabla_y g(x^*, y^*)$$

- The above formula is **problem-specific** and perhaps **#scaring**
- By rewriting

$$\Phi(y^*) = \min\{f(x, \mathbf{q}) \mid g(x, \mathbf{q}) \le 0, \, y^* \le \mathbf{q} \le y^*\}$$

we obtain a much **simpler recipe** to derive the same Benders cut:

- 1) solve the original convex problem with new var. bounds $y^* \le y \le y^*$
- 2) take opt_val and reduced costs r_j 's
- 3) write $w \ge opt_val + \sum_j r_j(y_j y_j^*)$

Benders feasibility cuts

• For some important applications, the set

$$X(y) := \{ x : g(x, y) \le 0 \}$$

can be empty for some "infeasible" $y \in S$

$$\rightarrow \quad \Phi(y) := \min_{x \in X(y)} f(x, y)$$
 undefined

• This situation can be handled by considering the "phase-1" feasibility condition

$$0 \ge \Psi(y) := \min\{1^T s \, | \, g(x, y) \le s, \, s \ge 0\}$$

where the function $\Psi(y)$ is **convex**

→ it can be approximated by the usual (sub)gradient "feasibility cut"

$$0 \ge \Psi(y) \ge \Psi(y^*) + \xi(y^*)^T (y - y^*)$$

to be computed by the same machinery as the usual "optimality cut"

$$w \ge \Phi(y) \ge \Phi(y^*) + \xi(y^*)^T (y - y^*)$$

Successful Benders applications

- Benders decomposition works well when fixing $y=y^*$ for computing $\Phi(y^*)^*$ makes the problem **much simpler to solve**.
- This usually happens when

- The problem for $y=y^*$ decomposes into a number of independent subproblems $\min \sum_{i \in I} f_i y_i + \sum_{i \in I} \sum_{j \in I} c_{ij} x_{ij}$

- Stochastic Programming $s.t. \sum_{i \in I} x_{ij} = 1$ $\forall j \in J$
- Uncapacitated Facility Location $x_{ij} \le y_i$ $x_{ij} \ge 0$
 - etc. $x_{ij} \ge 0$ $\forall i \in I, j \in J$ $y_i \in \{0,1\}$ $\forall i \in I$
- Fixing y=y* changes the nature of some constraints:
 - in Capacitated Facility Location, tons of contr.s of the form $x_{ij} \le y_j$ become just variable bounds

 $\forall i \in I, j \in J$

- Second Order Constraints $x_{ij}^2 \leq z_{ij} y_i$ become quadratic contr.s
- etc.

That's it ... or not?

- In practice, Benders decomposition can work quite well, but sometimes it is **desperately slow**
 - ... as the root node bound does not improve even

 Slow convergence is generally attributed to the poor quality of Benders cuts, to be cured by a more clever selection policy (Pareto optimality of Magnanti and Wong, 1981, etc.) but there is more...

Role of the cut loop

- B&C codes generate cuts, on the fly, in a **sequential** fashion \bullet
- Consider e.g. the **root B&C node** (arguably, the most critical one) ۲
- A classical **cut-loop scheme** (described here for MILPs) \bullet

J. E. Kelley. The cutting plane method for solving convex programs, Journal of the SIAM, 8:703-712, 1960.

- Find an optimal vertex x* of the current LP relaxation
- Invoke a separation function on x^* , add the returned violated cut (if any) to the current LP, and repeat
- Can be very **ineffective** in the **first iterations** • when few constraints are specified, and x^* moves along an **unstable zig-zag trajectory**

.... which is precisely what often happens with Benders cuts

But... alternative cut loops do exist!

- Kelley's cut loop implemented in standard MI(L)P solvers:
 - PROS: natural, efficient reopt., often works well
 - CONS: can be VERY ineffective, e.g., in column generation or in some under-constrained cutting plane methods
- Ellipsoid & Analytic Center cut loops: kind of binary search in the multi-dimensional space: at each iteration, a core point q "well inside" the current relaxation is computed and separated
 - CONS: q can be difficult to find and to separate
 - PROS: overall convergence does not depend
 on the quality of the cut (facets not required here!)
- Cheaper alternatives often preferred: bundle (Lemaréchal) or in-out (Ben-Ameur and Neto) methods

Stabilizing Benders can be easy!

- To summarize:
 - Benders cut machinery is easy to implement ...
 - ... but the root node cut loop can be **very critical** → many implementations sank here!

- Kelley's cut loop can be **desperately slow**
- Stabilization using "interior points" is a must
 → this is well-known in subgradient optimization and Dantzig-Wolfe
 - decomposition (column generation), but holds for Benders as well
- E.g., for facility location problems, we implemented a very simple "chase the carrot" heuristic to determine a stabilized path towards the optimal *y*
- Akin to Nesterov's Accelerated Gradient descent method

Our #ChaseTheCarrot heuristic

- We (the donkey) start with y = (1,1,...,1) and optimize the master LP as in Kelley, to get optimal y* (the carrot on the stick).
- We move *y* just **half-way** towards *y**. We then separate a point *y*' in the segment **[***y*, *y****]** close to the new *y*.

- The generated Benders cut is added to the master LP, which is reoptimized to get the new optimal **y*** (carrot moves).
- Repeat until bound improves, then switch to Kelley for final bound refinement (kind of cross-over)
- Warning: adaptations needed if feasibility Benders cuts can be generated...

Effect of the improved cut loop

- Comparing Kelley cut loop at the root node with Kelley+ (add epsilon to y*) and with our chase-the-carrot method (inout)
- Koerkel-Ghosh **qUFL** instance gs250a-1 (250x250, quadratic costs)
- *nc = n. of Benders cuts generated at the end of the root node
- times in logarithmic scale

Conclusions

To summarize:

• Benders cuts are **easy** to implement within modern B&C (just use a callback where you solve the problem for $y=y^*$ and compute reduced costs)

- Kelley's cut loop can be **desperately slow** hence stabilization is a **must**
- Implementations in **general** MIP solvers expected soon (already in Cplex 12.7)
