Chapter 7

NP Completeness

Exercise 7.1  Show that an algorithm that makes at most a constant number of calls to polynomial-time subroutines runs in polynomial time, but that a polynomial number of calls to polynomial-time subroutines may result in an exponential-time algorithm.

Answer: Suppose without loss of generality that algorithm $A$ consists of a sequence of calls to subroutines $S_1, \ldots, S_m$, with each subroutine called once in that order. Assume that each subroutine $S_i$ has a (polynomial) running time bounded by $p_i(n)$, with $p_i(n) \leq p(n) = n^k$.

Note that $A$ might call $S_1$ on its input, then call $S_2$ on the return value provided by $S_1$, and so on until $S_m$ is called on the value provided by $S_{m-1}$. We show by induction that the largest size of the return value and the worst-case running time of the $i$-th call are both $O(p_i(n))$, with

$$p^i(n) = p(p(\ldots(p(n))\ldots)) = n^{k^i}.$$  

For $i = 1$, the argument of $S_1$ is of size at most $n$. Since $S_1$ has running time $O(p(n))$, its return value has also size $O(p^1(n)) = O(n^k)$. Assume that the proposition holds for any $i < m$, and consider the $(i+1)$-th call. By the inductive hypothesis, the size of the argument of $S_{i+1}$ has size $O(p^i(n))$. Since $S_{i+1}$ has running time $O(p(n))$, the running time of the $(i+1)$-th call and the size of the return value are both $O\left((p^i(n))^{k^i}\right) = O(p^{i+1}(n))$.

The inductive thesis follows.

After the $m$-th call, we have taken time

$$O\left(\sum_{i=1}^{m} p^i(n)\right) = O(mp^m(n)) = O\left(mn^{k^m}\right),$$

which is polynomial for any constant $k$ and $m$. 

On the other hand, suppose that \( A \) simply makes \( n \) nested calls to a subroutine \( S \), i.e., on input \( n \), \( A \) computes

\[
\underbrace{S(n)}_{\text{n times}} = S(S(\ldots(S(n))\ldots)).
\]

Suppose that \( S \) takes linear time and that its return value is twice as long as its input. It follows that the running time and the size of the return value of the \( i \)-th call are both \( \Theta(n2^i) \). Therefore, the total running time is

\[
\Theta \left( n \sum_{i=1}^{n} 2^i \right) = \Theta(n2^n).
\]

\[\square\]

**Exercise 7.2** Prove that the class \( NP \) of languages is closed under the following operations:

(a) Union of two languages.

(b) Intersection of two languages.

(c) Concatenation of two languages.

(d) Kleene star of a language.

**Answer:** Observe that we can re-state the definition of \( L \in NP \) as follows:

**Definition** A language \( L \) is in \( NP \) iff there exists a verification algorithm \( A \), and polynomials \( p, q \) such that:

- \( L = L_A \);
- \( \forall x \in L, \exists y \text{ such that } |y| \leq p(|x|) \text{ and } A(x, y) = 1; \)
- \( A \) on input \((x, y)\) halts in time \( \leq q(|x| + |y|) \).

In what follows we use the notation \((p + q)(n)\) to denote the polynomial whose value on \( n \) is \( p(n) + q(n) \).

(a) Let \( L_1, L_2 \in NP \), with verification algorithms \( A_1, A_2 \) (i.e., \( L_1 = L_{A_1}, L_2 = L_{A_2} \)), and polynomial bounds \( p_1, q_1, \) and \( p_2, q_2 \), respectively.

Define a new verification algorithm \( A \) as follows:
Note that $A(x, y) = 1$ iff $A_1(x, y) = 1$ or $A_2(x, y) = 1$. We have:

1. $L_1 \cup L_2 \subseteq L_A$. Let $x \in L_1 \cup L_2$. Then $x \in L_1$ or $x \in L_2$. If $x \in L_1$, then $\exists y$ such that $A_1(x, y) = 1$. Hence, $A(x, y) = 1$. Otherwise, if $x \in L_2$, then $\exists y$ such that $A_2(x, y) = 1$. Hence, $A(x, y) = 1$. Therefore $x \in L_A$.

2. $L_A \subseteq L_1 \cup L_2$. Let $x \in L_A$. Then $\exists y$ such that $A(x, y) = 1$. This implies that either $A_1(x, y) = 1$ or $A_2(x, y) = 1$, that is, $x \in L_{A_1}$ or $x \in L_{A_2}$. Therefore $x \in L_{A_1} \cup L_{A_2} = L_1 \cup L_2$.

3. $\forall x \in L_A, \exists y$ such that $A(x, y) = 1$. If $x \in L_1$, we have $|y| \leq p_1(|x|)$. If $x \in L_2$, we have $|y| \leq p_2(|x|)$. Therefore $|y| \leq p_1(|x|) + p_2(|x|) = (p_1 + p_2)(|x|)$.

4. $A$ on $(x, y)$ takes time $O((q_1 + q_2)(|x| + |y|))$ and is therefore polynomially bounded. This proves that $L_1 \cup L_2 \in \text{NP}$.

(b) Let $L_1, L_2 \in \text{NP}$, with verification algorithms $A_1, A_2$, and polynomial bounds $p_1, q_1$ and $p_2, q_2$, respectively. Moreover, let $\#$ be a distinguished character not in the alphabet of the certificates. Define a new verification algorithm $A$ as follows:

$$A(x, y)$$

if $y \neq y_1 \# y_2$

then return 0

if $A_1(x, y_1) = 1$

then if $A_2(x, y_2) = 1$

then return 1

return 0

Note that $A(x, y) = 1$ iff $y = y_1 \# y_2$ and $A_1(x, y_1) = A_2(x, y_2) = 1$. We have:

1. $L_1 \cap L_2 \subseteq L_A$. Let $x \in L_1 \cap L_2$. Then $x \in L_1$ and $x \in L_2$. Then, $\exists y_1, y_2$ such that $A_1(x, y_1) = 1$ and $A_2(x, y_2) = 1$. This implies that $A(x, y_1 \# y_2) = 1$. Therefore $x \in L_A$.

2. $L_A \subseteq L_1 \cap L_2$. Let $x \in L_A$. Then $\exists y_1 \# y_2$ such that $A(x, y_1 \# y_2) = 1$. This implies that $A_1(x, y_1) = 1$ and $A_2(x, y_2) = 1$. Hence $x \in L_{A_1}$ and $x \in L_{A_2}$. Therefore, $x \in L_1 \cap L_2$. 

3
3. \( \forall x \in L_A, \exists y \) such that \( A(x, y) = 1 \). Moreover, since \( y = y_1 \# y_2 \), with \( |y_1| \leq p_1(|x|) \) and \( |y_2| \leq p_2(|x|) \), we have \( |y| = |y_1| + |y_2| + 1 \leq (p_1 + p_2)(|x|) + 1 \). Therefore \( |y| \) is polynomially bounded.

4. \( A \) on \((x, y)\) runs in time \( O((q_1 + q_2)(|x| + |y|)) \).

This proves that \( L_1 \cap L_2 \in \text{NP} \).

(e) Given a string \( x \), let \( x_{i...j} \) denote the substring of \( x \) (of length \( j - i + 1 \)) from the \( i \)th to the \( j \)th character. Define \( x_{i...j} = \varepsilon \) if \( i > j \). Let \( L_1, L_2 \in \text{NP} \), with verification algorithms \( A_1, A_2 \), and polynomial bounds \( p_1, q_1 \) and \( p_2, q_2 \), respectively. Moreover, let \( \# \) be a distinguished character not in the alphabet of the certificates. Define a new verification algorithm \( A \) as follows:

\[
A(x, y) \\
\text{if } y \neq y_1 \# y_2 \\
\quad \text{then return } 0 \\
\text{for } k \leftarrow 0 \textbf{ to } |x| \textbf{ do} \\
\quad \text{if } A_1(x_{1...k}, y_1) = 1 \text{ and } A_2(x_{k+1...|x|}, y_2) = 1 \\
\quad \quad \text{then return } 1 \\
\text{return } 0
\]

Note that \( A(x, y) = 1 \) iff \( y = y_1 \# y_2 \) and \( \exists 0 \leq k \leq |x| \) such that \( A_1(x_{1...k}, y_1) = 1 \) and \( A_2(x_{k+1...|x|}, y_2) = 1 \). We have:

1. \( L_1 L_2 \subseteq L_A \). Let \( x \in L_1 L_2 \). Then \( \exists 0 \leq k \leq |x| \) such that \( x_{1...k} \in L_1 \) and \( x_{k+1...|x|} \in L_2 \). Hence, \( \exists y_1, y_2 \) such that \( A_1(x_{1...k}, y_1) = 1 \) and \( A_2(x_{k+1...|x|}, y_2) = 1 \). So, \( A(x, y_1 \# y_2) = 1 \), i.e. \( x \in L_A \).

2. \( L_A \subseteq L_1 L_2 \). This is immediate from our definition of \( A \).

3. \( \forall x \in L_A, \exists y \) such that \( A(x, y) = 1 \) and \( |y| \leq (p_1 + p_2)(|x|) + 1 \).

4. When running \( A \) on \((x, y)\), there are at most \( |x| + 1 \) executions of \( A_1 \), each taking time \( \leq q_1(|x| + |y|) \), and at most \(|x| + 1 \) executions of \( A_2 \), each taking time \( \leq q_2(|x| + |y|) \). So, \( A \) has a polynomial time bound \( O(|x|(q_1 + q_2)(|x| + |y|)) \).

This proves that \( L_1 L_2 \in \text{NP} \).
(d) We can exploit the advantage of guessing the right certificate by encoding the substring divisions of $x$ in the certificate $y$. Namely, let $\#$, $\&$ be distinguished characters not in the alphabet of the certificates. A certificate for a string $x$ in $L^*$ will be of type

$$y = y_1\#y_2\# \ldots \#y_k\#m_1\&m_2\& \ldots \&m_{k-1},$$

where $1 \leq k \leq |x|$, $m_0 = 0 \leq m_1 \leq \ldots m_{k-1} \leq m_k = |x|$, and, for any $i$, $1 \leq i \leq k$, $y_i$ is a potential certificate for $x_{m_{i-1}+1 \ldots m_i}$’s membership in $L$. Define a new verification algorithm $A$ as follows:

$$A(x, y)$$

for $k \leftarrow 1$ to $|x|$ do

$m_0 \leftarrow 0, m_k \leftarrow |x|$ if $y = y_1\#y_2\# \ldots \#y_k\#m_1\&m_2\& \ldots \&m_{k-1}$

then $t \leftarrow \text{true}$

for $i \leftarrow 1$ to $k$ do

$\text{do } t \leftarrow \text{false}$

$A_0(x_{m_{i-1}+1 \ldots m_i}, y_i)$

if $t$ then return $1$

return $0$

$A(x, y) = 1$ iff $\exists k, 1 \leq k \leq |x|$, such that $y = y_1\#y_2\# \ldots \#y_k\#m_1\&m_2\& \ldots \&m_{k-1}$ and, for any $i$, $1 \leq i \leq k$, $A_0(x_{m_{i-1} \ldots m_i}, y_i) = 1$. We have:

1. $L^* \subseteq L_A$. Let $x \in L^*$. Then there is a value $k, 1 \leq k \leq |x|$, such that $x$ is the concatenation of strings $x_{m_{i-1}+1 \ldots m_i} \in L$, for $1 \leq i \leq k$. Then, for each such $i$ there is a $y_i$ such that $A_0(x_{m_{i-1} \ldots m_i}, y_i) = 1$. Thus, if $y = y_1\#y_2\# \ldots \#y_k\#m_1\&m_2\& \ldots \&m_{k-1}$, we have $A(x, y) = 1$. Therefore, $x \in L_A$.

2. $L_A \subseteq L^*$. Let $x \in L_A$. Then, there is a $y = y_1\#y_2\# \ldots \#y_k\#m_1\&m_2\& \ldots \&m_{k-1}$ such that $A(x, y) = 1$. By our definition of $A$, this implies that $x_{m_{i-1} \ldots m_i} \in L$ for any $i$, $1 \leq i \leq k$. Therefore, $x \in L^*$.

3. Since there are at most $|x| y_i$’s, with $|y_i| \leq p_0(|x|)$, and at most $|x| m_i$’s, with $|m_i| \leq \log |x|$, and at most $2|x|$ extra-characters in $y$, we have $|y| = O(|x| (p_0(|x|) + \log |x| + 2))$, which is polynomially bounded.

4. $A$ on $(x, y)$ runs $A_0$ at most $|x|$ times (because $k \leq |x|$), each taking time $\leq q_0(|x| + |y|)$. Thus, $A$ runs in time $O(|x|q_0(|x| + |y|))$, and is therefore polynomially bounded.

This proves that $L^* \in NP$. \qed
**Exercise 7.3** Prove that \( <_P \) is a transitive relation. That is, for \( L_1, L_2, L_3 \subseteq \{0, 1\}^* \),
\[
(L_1 <_P L_2 \text{ and } L_2 <_P L_3) \Rightarrow L_1 <_P L_3.
\]

**Answer:** Let \( f(x), g(x) \) denote the polynomial-time computable functions that reduce \( L_1 \) to \( L_2 \) and \( L_2 \) to \( L_3 \), respectively. Let \( h(x) = g(f(x)) \). For all strings \( x \in \{0, 1\}^* \) we have:
\[
x \in L_1 \text{ iff } f(x) \in L_2
\]
\[
y = f(x) \in L_2 \text{ iff } g(y) = g(f(x)) \in L_3
\]
Hence
\[
x \in L_1 \text{ iff } h(x) = g(f(x)) \in L_3.
\]
Note that \( h(x) = g(f(x)) \) is polynomial-time computable, since it is the composition of two polynomial-time computable functions. This proves that \( L_1 <_P L_3 \). \( \square \)

**Exercise 7.4** We say that a function \( f \) is computable in quasi linear time \( T_f(n) \) if there are nonnegative constants \( c \) and \( k \) such that \( T_f(n) \leq cn(\log n)^k \). Show that reducibility in quasi linear time is a transitive relation.

**Answer:** Consider three languages \( L_1, L_2 \) and \( L_3 \) such that \( L_1 \) is reducible in quasi linear time to \( L_2 \), and \( L_2 \) is reducible in quasi linear time to \( L_3 \). By the definition of reduction, there exist reduction functions \( f \) from \( L_1 \) to \( L_2 \) computable in quasi linear time \( T_f(n) \leq cf n(\log n)^{k_f} \), and \( g \) from \( L_2 \) to \( L_3 \) computable in quasi linear time \( T_g(n) \leq cg n(\log n)^{k_g} \). In the previous exercise, we have shown that \( h(x) = g(f(x)) \) is a reduction function from \( L_1 \) to \( L_3 \). It remains to show that \( h(x) \) is computable in quasi linear time.

Let \( y = f(x) \) and \( h(x) = g(y) \). Let also \( |x| = n \). We have \( |y| \leq T_f(|x|) \leq cf n(\log n)^{k_f} \). Therefore, \( h(x) = g(y) \) can be computed in time
\[
T_h(n) \leq T_f(n) + T_g(T_f(n))
\]
\[
= cf n(\log n)^{k_f} + cg \left( cf n(\log n)^{k_f} \right) \left( \log \left( cf n(\log n)^{k_f} \right) \right)^{k_g}
\]
\[
= (c_g cf) n (\log n)^{k_f + k_g} (1 + o(1))
\]
Therefore, there exist constants \( c_h > c_g cf \) and \( k_h = k_f + k_g \) such that \( T_h(n) \leq c_h n(\log n)^{k_h} \). This shows that \( L_1 \) is reducible in quasi linear time to \( L_3 \). \( \square \)
Exercise 7.5  Prove that \( L \leq_P L^c \) iff \( L^c \leq_P L \).

Answer:

\[
f \text{ reduces } L \text{ to } L^c \iff \forall x \in \Sigma^* : x \in L \iff f(x) \in L^c \\
\iff \forall x \in \Sigma^* : (x \notin L) \iff (f(x) \notin L^c) \\
\iff \forall x \in \Sigma^* : x \in L^c \iff f(x) \in L \\
\iff f \text{ reduces } L^c \text{ to } L.
\]

Exercise 7.6  Under the assumption that \( P \neq NP \), prove or disprove the following statements:

(a) \( \{0,1\}^* \in P \).

(b) There are \( NP \)-complete languages that are regular. Recall that a regular language is one which is accepted by a Deterministic Finite-State Automaton (DFSA).

(c) If \( L \) contains an \( NP \)-complete subset, then \( L \) is \( NP \)-complete.

(d) All \( NP \)-Complete problems can be solved in time \( O\left(2^{p(n)}\right) \), for some polynomial \( p(n) \).

(e) The halting problem is \( NP \)-complete.

(f) The halting problem is \( NP \)-hard.

Answer:

(a) True  \( \{0,1\}^* \) is decided by the following constant-time algorithm:

\[
A_{\{0,1\}^*}(x) \\
\text{return 1}
\]

(b) False  Given a regular language \( L \), any DFSA that accepts \( L \) yields a linear-time decision algorithm \( A_L \) for \( L \). To see this, associate a distinct label to each state and use conditional jumps to “simulate” transitions. On string \( x \), we will perform exactly \( |x| \) jumps before either accepting or rejecting, according to whether the last jump leads to a final or a nonfinal state. This proves that for any regular language \( L, L \in P \).
(c) **False** Counterexample: \( \{0, 1\}^* \supset L_{\text{SAT}} \), but Point (a) proves that \( \{0, 1\}^* \in P \).

(d) **True** For \( L \in NP \), let \( A_L \) be the polynomial-time algorithm verifying \( L \) and running in time \( T_A(|x| + |y|) \leq c_1(|x| + |y|)^k \), where \( |y| \leq c_2|x|^k \) when \( x \in L \). We can write the following decision algorithm for \( L \):

\[
\text{DECIDE}_L(x) \\
\text{for each } y \in \{0, 1\}^*, |y| \leq c_2|x|^k \text{ do} \\
\text{if } A_L(x, y) = 1 \text{ then return 1} \\
\text{return 0}
\]

\( \text{DECIDE}_L(x) \) returns 1 if and only if there exists a “short” certificate for \( x \), which is the case if and only if \( x \in L \). Therefore \( \text{DECIDE}_L \) decides \( L \). The running time of \( \text{DECIDE}_L(x) \) is \( O(|x|^{hk}2^{c_2|x|^k}) = O(2^{c_2|x|^k+|x|}) = O(2^{p(|x|)}) \).

(e) **False** Recall that the halting problem corresponds to the following language:

\[ L_H = \{ y \in \{0, 1\}^* : y = \langle M, x \rangle, M \text{ is a Turing machine which terminates on input } x \} \]

We know that \( L_H \) is an undecidable language. On the other hand, since \( NPC \subseteq NP \), Point (d) proves that any \( NP \)-Complete problem is decidable. Therefore the halting problem cannot be \( NP \)-Complete.

(f) **True** Consider an arbitrary language \( L \in NP \), and let \( \text{DECIDE}_L \) be the exponential decision algorithm for \( L \) developed in Point (d). Consider the following program, based on \( \text{DECIDE}_L \):

\[ A_L(x) \]

\[
\begin{array}{l}
\text{if } \text{DECIDE}_L(x) = 1 \\
\text{then return 1} \\
\text{else while true do} \\
\{ \text{loop forever } \}
\end{array}
\]

\( A_L \) either returns 1 or goes into an infinite loop. Let \( M_{A_L} \) be a Turing Machine encoding algorithm \( A_L \). Define the following function:

\[ f(x) = \langle M_{A_L}, x \rangle \]

Clearly, \( f \) is computable in polynomial time, since it takes constant time to encode the Turing Machine and linear time to copy the input string. We now prove that \( f \) reduces \( L \)
to $L_H$, the language of the halting problem. We have

$$x \in L \iff \text{DECIDE}_L(x) = 1 \iff A_L(x) \text{ terminates} \iff \langle M_{A_L}, x \rangle \in L_H$$

We have proved that for any language $L \in NP$, $L \not<^PL_H$. Hence $L_H$ is NP-Hard. \qed

**Exercise 7.7** Suppose that someone gives you a polynomial-time algorithm to decide formula satisfiability. Describe how to use this algorithm to find satisfying assignments in polynomial time.

**Answer:** Let $\Phi(x_1,\ldots,x_m)$ be a boolean formula, and let SAT be a (rather unlikely) subroutine deciding satisfiability in polynomial time $O(p(n))$, where $n \geq m$ is the size of formula $\Phi$. We can find a satisfying assignment to $\Phi$ (assuming that there is one, which can be ascertained with one call to SAT) by iteratively finding a truth assignment $s(1)$ for $x_1$, then finding an assignment $s(2)$ for $x_2$, and so on until we have an assignment for all the variables. Our invariant will be that after the $i$-th iteration, the formula $\Phi(s(1),\ldots,s(i),x_{i+1},\ldots,x_m)$ (i.e., the formula where the variables $x_1,\ldots,x_i$ are substituted with the boolean constants $s(1),\ldots,s(i) \in \{\text{false, true}\}$) is satisfiable.

The algorithm works as follows: having found assignments $s(1),s(2),\ldots,s(i-1)$ for the first $i-1$ variables, we call SAT on $\Phi(s(1),\ldots,s(i-1),\text{false},x_{i+1},\ldots,x_m)$. If this formula is satisfiable, then $s(i) = \text{false}$. If the formula is not satisfiable, then $s(i) = \text{true}$. In the latest case, $\Phi(s(1),\ldots,s(i-1),\text{true},x_{i+1},\ldots,x_m)$ must be satisfiable, because our loop invariant/induction hypothesis tells us that $\Phi(s(1),\ldots,s(i-1),x_1,\ldots,x_m)$ is satisfiable (and $\Phi(s(1),\ldots,s(i-1),\text{false},x_{i+1},\ldots,x_m)$ is not). The algorithm follows:

```plaintext
FIND_ASSIGNMENT(\Phi(x_1,x_2,\ldots,x_m))
if SAT(\Phi(x_1,x_2,\ldots,x_m))= "no"
    then return "formula is not satisfiable"
for i ← 1 to m
    do s[i] ← false
    if SAT(\Phi(s[1],\ldots,s[i],x_{i+1},\ldots,x_m)) = "no"
        then s[i] ← true
return s
```

At stage $i$, it takes polynomial time to prepare $\Phi(s(1),\ldots,s(i),\text{false},x_{i+2},\ldots,x_m)$; then SAT takes time $p(n)$ to decide the satisfiability of this formula. Since there are $m = O(n)$ iterations, the overall running time is polynomial. \qed
Exercise 7.8  Consider the following decision problem:

**BI_{SAT} (DOUBLE SATISFIABILITY):**

**INSTANCE:** $\langle \Phi(x_1, x_2, \ldots, x_n) \rangle$, $\Phi$ is a boolean formula

**QUESTION:** Are there two distinct satisfying assignments for $\Phi$?

Show that $\text{BI}_{SAT}$ is $NP$-Complete.

**Answer:** Let us first show that $\text{BI}_{SAT} \in NP$. Consider the following straightforward algorithm.

\[
\text{VERIFY}_{\text{BI}_{SAT}}(x, y) \\
\text{if } x \neq \langle \Phi(x_1, x_2, \ldots, x_n) \rangle \text{ then return } 0 \\
\text{if } y \neq \langle (b_1^1, b_1^2, \ldots, b_n^1), (b_1^2, b_2^2, \ldots, b_n^2) \rangle \text{ then return } 0 \\
\{ \text{the } b_i^j \text{'s are boolean values that form two} \\
\text{truth assignments for the variables of } \Phi \} \\
same \leftarrow \text{true} \\
\text{for } i \leftarrow 1 \text{ to } n \text{ do same } \leftarrow \text{same and } (b_1^i = b_2^i) \\
\text{if same then return } 0 \\
\{ \text{truth assignments must be distinct} \} \\
\text{if } \Phi(b_1^1, b_2^1, \ldots, b_n^1) \text{ and } \Phi(b_1^2, b_2^2, \ldots, b_n^2) \\
\text{ then return } 1 \\
\text{return } 0
\]

The algorithm performs two evaluations of $\Phi$ plus some extra steps whose number is linear in $|\langle \Phi \rangle|$. Since a boolean formula can be evaluated in time polynomial in its length, $\text{VERIFY}_{\text{BI}_{SAT}}$ verifies $\text{BI}_{SAT}$ in polynomial time.

The second step is to show that $\text{BI}_{SAT}$ is $NP$-Hard. We show that $\text{SAT} \leq_p \text{BI}_{SAT}$, where $\text{SAT}$ is the Boolean Formula Satisfiability problem.

Let $\Phi(x_1, x_2, \ldots, x_n)$ be a formula, and let $x_{n+1}$ be a new variable. We define our reduction function as follows:

\[
f(\langle \Phi(x_1, x_2, \ldots, x_n) \rangle) = \langle \Phi(x_1, x_2, \ldots, x_n) \land (x_{n+1} \lor \lnot x_{n+1}) \rangle.
\]

Let us show that

\[
\langle \Phi(x_1, x_2, \ldots, x_n) \rangle \in \text{SAT} \iff f(\langle \Phi(x_1, x_2, \ldots, x_n) \rangle) \in \text{BI}_{SAT}.
\]

Suppose $\Phi(x_1, x_2, \ldots, x_n) \in \text{SAT}$. Then there is a truth assignment $(b_1, b_2, \ldots, b_n)$ to variables $(x_1, x_2, \ldots, x_n)$ satisfying $\Phi(x_1, x_2, \ldots, x_n)$. Since $(x_{n+1} \lor \lnot x_{n+1})$ is true for both
\[ x_{n+1} = \text{false} \] and \[ x_{n+1} = \text{true} \], we have that \( f(\Phi(x_1, x_2, \ldots, x_n)) \) is satisfied by the two assignments \((b_1, b_2, \ldots, b_n, \text{false})\) and \((b_1, b_2, \ldots, b_n, \text{true})\). Conversely, if \( f(\Phi(x_1, x_2, \ldots, x_n)) \) has two satisfying assignments \((b_1^1, \ldots, b_n^1, b_{n+1}^1)\) and \((b_1^2, \ldots, b_n^2, b_{n+1}^2)\) then \( \Phi(x_1, x_2, \ldots, x_n) \) is clearly satisfied by both assignments \((b_1^1, b_2^1, \ldots, b_n^1)\) and \((b_1^2, b_2^2, \ldots, b_n^2)\), since, in order for \( \Phi(x_1, x_2, \ldots, x_n) \land (x_{n+1} \lor \neg x_{n+1}) \) to be true, both operands \( \Phi(x_1, x_2, \ldots, x_n) \) and \((x_{n+1} \lor \neg x_{n+1})\) must be true.

Finally, note that \( f \) creates a new variable \( x_{n+1} \) and computes the encoding of the new formula. Such activity can be accomplished in time polynomial in \(|\langle \Phi(x_1, x_2, \ldots, x_n) \rangle|\).

**Exercise 7.9** Consider the following decision problem:

**M\text{\_SAT} (MAJORITY SATISFIABILITY):**

**INSTANCE:** \( \langle \Phi(x_1, x_2, \ldots, x_n) \rangle \), \( \Phi \) is a boolean formula

**QUESTION:** Is \( \Phi(x_1, x_2, \ldots, x_n) \) true for more than a half of the possible \( 2^n \) input assignments?

Show that \( M\text{\_SAT} \) is NP-hard.

**Answer:** We show that SAT \( \prec_p M\text{\_SAT} \). Given a formula \( \Phi(x_1, x_2, \ldots, x_n) \), define

\[
f(\langle \Phi(x_1, x_2, \ldots, x_n) \rangle) = \langle \Phi'(x_1, x_2, \ldots, x_n, x_{n+1}) \rangle,
\]

with

\[
\Phi'(x_1, x_2, \ldots, x_n, x_{n+1}) = \Phi(x_1, x_2, \ldots, x_n) \lor x_{n+1}.
\]

Note that \( f \) is trivially computable in time polynomial in \(|\langle \Phi(x_1, x_2, \ldots, x_n) \rangle|\).

Let us show that \( f \) reduces SAT to \( M\text{\_SAT} \). First note that \( \Phi' \) is satisfied by any of the \( 2^n \) assignments \((x_1, x_2, \ldots, x_n, \text{true})\). If \( \Phi \in \text{SAT} \), then there exists an assignment \((\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n)\) such that \( \Phi(\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n) = \text{true} \). Then, \( \Phi' \) is also satisfied by the assignment \((\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n, \text{false})\), for a total of at least \( 2^n + 1 = 2^{n+1}/2 + 1 \) satisfying assignments, therefore \( f(\langle \Phi \rangle) \in M\text{\_SAT} \). Vice versa, if \( \Phi \) is not satisfiable, then the assignments \((x_1, x_2, \ldots, x_n, \text{true})\) are all and only those satisfying \( \Phi' \). Since these are \( 2^n < 2^{n+1}/2 + 1 \), \( f(\langle \Phi \rangle) \not\in M\text{\_SAT} \). □

**Exercise 7.10** Consider the following decision problem:

**0-1 IP (0-1 INTEGER PROGRAMMING):**

**INSTANCE:** \( \langle A, b \rangle \), where \( A \) is an integer \( m \times n \) matrix and \( b \) is an integer \( m \)-vector.
QUESTION: Is there an $n$-vector $x$ with components in $\{0,1\}$ such that $(Ax)_i \geq b_i$, for $1 \leq i \leq m$?

Prove that 0-1 IP is $NP$-complete.

Answer: A certificate for an instance $(A, b)$ of 0-1 IP is clearly a 0-1 $\text{cols}(A)$-vector $x$. Here is the verification algorithm:

```plaintext
VERIFY_IP(a, y)
if (a ≠ ⟨A, b⟩) or (y ≠ ⟨x⟩) then return 0
m ← rows(A)
n ← cols(A)
if (length(b) ≠ m) or (length(x) ≠ n) then return 0
for i ← 1 to m do
  for j ← 1 to n do
    if (a_{i,j}, b_i noninteger) or (x_j ∉ \{0,1\}) then return 0
c ← MAT_VEC_MULT(A, x)
for i ← 1 to m do
  if c_i < b_i then return 0
return 1
```

VERIFY_IP$(a, y)$ is a legal verification algorithm for 0-1 IP, since it returns 1 if and only if $a$ is a well-formed encoding $⟨A, b⟩$ of an instance of IP, $y$ is a well formed encoding of a 0-1 $\text{cols}(A)$-vector $x$, and $Ax \geq b$. Moreover, since matrix-vector multiplication can be performed in polynomial time, the algorithm is clearly polynomial.

To show 0-1 IP is NP-hard, we show that 3-CNF-SAT $\leq_P$ 0-1 IP. Let $Φ(x_1, x_2, \ldots x_n) = C_1 \land C_2 \land \cdots \land C_k$ be a boolean formula in 3-CNF made of $k$ clauses. Without loss of generality, in what follows we assume than no clause $C_j$ contains both $x_i$ and $\overline{x_i}$, since in this case $C_j$ is a tautology and can be eliminated from $Φ$ without affecting the value of the formula on any of the assignments. We will say that $x_i = 1$ if $x_i$ is assigned the value $\text{true}$, and $x_i = 0$ if $x_i$ is assigned the value $\text{false}$. If a boolean variable has value $x_j = \alpha$, with $\alpha \in \{0,1\}$, then the value of $\overline{x_j}$ is $(1-\alpha)$. With this convention, a 0-1 $n$-vector can be seen as a truth assignment to the $n$ boolean variables of $Φ$.

From our instance $Φ$ of 3-CNF-SAT, we build an instance $(A, b)$ of 0-1 IP in the following way:

- $A$ is a $k \times n$ matrix, where row $i$ is built from clause $C_i$ of $Φ$ in the following way: if boolean variable $x_j$ does not appear in $C_i$, then $a_{i,j} = 0$. If $x_j$ is a literal in $C_i$, then $a_{i,j} = 1$. If $\overline{x_j}$ is a literal in $C_i$, then $a_{i,j} = -1$. 

• \( \mathbf{b} \) is a \( k \)-vector such that \( b_i = 1 - |\{ \text{negative literals in } C_i \}| \).

Given the above definition of \( A \) and \( \mathbf{b} \), for \( 1 \leq i \leq k \), the \( i \)-th inequality \((Ax)_i \geq b_i\) can be rewritten as follows:

\[
\sum_{x_j \in C_i} x_j + \sum_{\neg x_j \in C_i} (1 - x_j) \geq 1.
\] (7.1)

Assume now that \( \Phi \) is satisfiable. Then there must exist a truth assignment to the \( n \) variables such that satisfies all clauses. Let \( (t_1, t_2, \ldots, t_n) \) be the 0-1 \( n \)-vector corresponding to such assignment. Then, the sum of the values \( \alpha_1^i, \alpha_2^i, \alpha_3^i \) of the three literals in each clause \( C_i \) dictated by the \( t_j \)'s is at least 1. Hence, all inequalities are satisfied at the same time by setting \( x_j = 1 \) if \( t_j = \text{true} \), and \( x_j = 0 \) otherwise. Vice versa, any 0-1 \( n \)-vector \((x_1, x_2, \ldots, x_n)\) satisfying all the \( k \) inequalities yields a satisfying truth assignment for \( \Phi \). Hence, \( f \) is a reduction from 3-CNF-SAT to IP.

Exercise 7.11  Consider the following decision problem:

**DF (DISTINCT FORMULAE):**

**INSTANCE:** \( \langle \Phi(x_1, x_2, \ldots, x_n), \Psi(x_1, x_2, \ldots, x_n) \rangle \),
with \( \Phi(x_1, x_2, \ldots, x_n) \) and \( \Psi(x_1, x_2, \ldots, x_n) \) boolean formulae.

**QUESTION:** Is there a truth assignment \((b_1, b_2, \ldots, b_n)\) such that \( \Phi(b_1, b_2, \ldots, b_n) \neq \Psi(b_1, b_2, \ldots, b_n) \)?

Show that DF is NP-complete.

**Answer:** We first show that DF \( \in \text{NP} \). A candidate certificate for DF is a truth assignment to the \( n \) variables. The verification algorithm VERIFY\_DF first checks whether its first input \( x = \langle \Phi(x_1, x_2, \ldots, x_n), \Psi(x_1, x_2, \ldots, x_n) \rangle \), that is, \( x \) is a well-formed encoding of an instance of DF; then checks that its second input encodes a truth assignment \((b_1, b_2, \ldots, b_n)\). If this is the case, then the algorithm checks whether \( \Phi(b_1, b_2, \ldots, b_n) \neq \Psi(b_1, b_2, \ldots, b_n) \). The running time of VERIFY\_DF is clearly polynomial in the size of its inputs. For brevity, we omit the code of the algorithm.

In order to show that DF is NP-Hard, we provide a polynomial-time reduction from SAT to DF. Recall that an instance of SAT is \( \langle \Phi(x_1, x_2, \ldots, x_n) \rangle \) and the question is whether \( \Phi \) is satisfiable, that is, whether there is a truth assignment \((b_1, b_2, \ldots, b_n)\) such that \( \Phi(b_1, b_2, \ldots, b_n) = \text{true} \). Our reduction function is the following:

\[
f \left( \langle \Phi(x_1, x_2, \ldots, x_n) \rangle \right) = \langle \Phi(x_1, x_2, \ldots, x_n), \Psi(x_1, x_2, \ldots, x_n) = x_1 \land \neg x_1 \rangle.
\]
Note that the second formula in $f(\langle \Phi(x_1, x_2, \ldots, x_n) \rangle)$ is a contradiction, therefore its evaluation yields \textit{false} on all truth assignments.

Clearly, $f$ is computable in polynomial time. It remains to show that $f$ is indeed a reduction. Assume that $\langle \Phi(x_1, x_2, \ldots, x_n) \rangle \in \text{SAT}$. Then there is a truth assignment $(b_1, b_2, \ldots, b_n)$ such that $\Phi(b_1, b_2, \ldots, b_n) = \text{true}$. On such assignment, we have

$$\text{true} = \Phi(b_1, b_2, \ldots, b_n) \neq \Psi(b_1, b_2, \ldots, b_n) = \text{false},$$

hence $f(\langle \Phi(x_1, x_2, \ldots, x_n) \rangle) \in \text{DF}$. Vice versa, if $\langle \Phi(x_1, x_2, \ldots, x_n) \rangle \notin \text{SAT}$, then

$$\Phi(b_1, b_2, \ldots, b_n) = \Psi(b_1, b_2, \ldots, b_n) = \text{false},$$

on all truth assignments $(b_1, b_2, \ldots, b_n)$. Therefore $f(\langle \Phi(x_1, x_2, \ldots, x_n) \rangle) \notin \text{DF}$. \hfill \QED

\textbf{Exercise 7.12} Consider the following problem:

\begin{itemize}
  \item [\text{INSTANCE:}] $\langle G, h, k \rangle$, with $G$ an undirected graph and $h, k > 0$.
  \item [\text{QUESTION:}] Does $G$ contain two disjoint cliques of size $h$ and $k$?
\end{itemize}

\textbf{(a)} Show that \textsc{Two-Clique} is in $\text{NP}$.

\textbf{(b)} Show that \textsc{Two-Clique} is $\text{NP}$-hard.

\textbf{Answer:}

\textbf{(a)} Consider the following verification algorithm $A$.

\begin{verbatim}
A(x, y)
  if x \neq \langle G = (V, E), h, k \rangle, h, k > 0
    then return 0
  if y \neq \langle U_1, U_2 \rangle, U_1, U_2 \subset V
    then return 0
  if |U_1| = h and |U_2| = k and U_1 \cap U_2 = \emptyset
    then if IS_CLIQUE(G, U_1) and IS_CLIQUE(G, U_2)
      then return 1
    return 0
\end{verbatim}

Subroutine IS_CLIQUE($G, U$) checks the adjacency list of $G$ to make sure that $U$ is a clique. Clearly, $L_A = \textsc{Two-Clique}$. The length of an accepting certificate $y$ is clearly $O(|V|) = O(|x|)$. Finally, IS_CLIQUE($G, U$) can clearly be implemented in polynomial time, therefore $A$ is polynomial.
Let us consider the following reduction function $f$ from CLIQUE to TWO-CLIQUE.

$$f(\langle G = (V, E), h \rangle) = \langle G' = (V \cup \{u\}, E), h, 1 \rangle,$$

where $\langle G = (V, E), h \rangle$ is a CLIQUE instance and $u \notin V$. Note that $u$ is an isolated node in $G'$.

Let us first prove that $f$ is indeed a reduction. If $\langle G = (V, E), h \rangle \in$ CLIQUE then there is a subset $K$ of $V$ which forms an $h$-clique. Now, $K$ is also an $h$-clique in $G'$, and $\{u\}$ is a 1-clique in $G'$ disjoint from $K$. Therefore $\langle G', h, 1 \rangle = f(\langle G, h \rangle) \in$ TWO-CLIQUE. Consider now the case $f(\langle G, h \rangle) \in$ TWO-CLIQUE. If $h = 1$, then clearly $\langle G, h \rangle \in$ CLIQUE. Let now $h > 1$. Then there is an $h$-clique $K$ in $(V \cup \{u\}, E)$. Since $u$ is not adjacent to any other vertex in $V$, $u$ is not contained in the $h$-clique. Therefore $K$ is also an $h$-clique in $G$. So $\langle G, h \rangle \in$ CLIQUE. Finally, $f$ simply copies $G$ and adds an extra node, therefore $f$ is computable in linear time.

Exercise 7.13 Consider the following decision problems:

OMC (ODD-MAX-CLIQUE):
INSTANCE: $\langle G = (V, E) \rangle$, with $G$ an undirected graph.
QUESTION: Is the maximum clique size odd?

EMC (EVEN-MAX-CLIQUE):
INSTANCE: $\langle G = (V, E) \rangle$, with $G$ an undirected graph.
QUESTION: Is the maximum clique size even?

(a) Show that OMC $\prec$ EMC.

(b) Show that if EMC is NP-complete then OMC is NP-complete.

Answer:

(a) Let $G = (V, E)$ be an undirected graph, and let $G' = (V', E')$ be defined as follows:

$$V' = V \cup \{\alpha\}, \quad \alpha \notin V;$$

$$E' = E \cup \{\{\alpha, v\} : v \in V\}.$$
Let now $f(\langle G \rangle) = \langle G' \rangle$. Clearly, $f(\langle G \rangle)$ can be computed in time polynomial in $|V|$ and $|E|$. Let $M \subseteq V$ be a max-clique for $G$, and $M' \subseteq V'$ be a max-clique for $G'$. Then, the following two claims hold:

1. $\alpha \in M'$.
   
   If this were not the case, since $\{\alpha, u\} \in E'$ for each $u \in M'$, $M' \cup \{\alpha\}$ would be a clique of size strictly greater than $M'$, a contradiction.

   
   By Claim 1, $\alpha \in M'$ and $M' - \{\alpha\}$ is a clique for $G$. Hence
   
   $$|M| \geq |M'| - 1.$$

   $M \cup \{\alpha\}$ is a clique for $G'$. Hence
   
   $$|M'| \geq |M| + 1$$

From Claim 1 and Claim 2 we conclude that $G$ has an odd max clique if and only if $G'$ has an even max clique. This proves that $f$ reduces OMC to EMC. Therefore OMC $\leq_P$ EMC.

(b) Suppose that EMC is NP-complete. Then, from Part (a) it follows that OMC $\in$ NP. Therefore, it is sufficient to show that EMC $<_P$ OMC, which requires an identical argument to the one used in Part (a), since function $f$ also reduces EMC to OMC.

Exercise 7.14 Consider the following decision problem:

**IS (INDEPENDENT SET):**

**INSTANCE:** $G = (V, E), k$, with $G$ an undirected graph, and $k > 0$.

**QUESTION:** Is there a subset $S \subseteq V$, $|S| = k$, with $\{u, v\} \notin E$ for each $u, v \in S$?

(a) Show that IS is NP-Complete.

(b) Assume that you are given an $O(|V| + |E|)$ algorithm for IS. Show how to use the algorithm to determine the maximum size of an independent set in time $O((|V| + |E|) \log |V|)$.

**Answer:** In order to prove that IS $\in$ NP, consider the following verification algorithm $A$. 

---

16
Subroutine IS_INDEPENDENT($G, U$) checks the adjacency list of $G$ to make sure that $U$ is an independent set. Clearly, $L = IS$. The length of an accepting certificate $y$ is $O(|V|) = O(|x|)$. Finally, IS_INDEPENDENT($G, U$) can clearly be implemented in polynomial time, therefore $A$ is polynomial.

Next we show that CLIQUE $\leq_P$ IS, hence IS is NP-hard. Consider the following transformation:

$$f ((G = (V, E), k)) = (G^c = (V, E^c), k),$$

where $E^c = \{\{u, v\} : u \neq v \in V \text{ and } \{u, v\} \notin E\}$. Then:

1. Since there is an edge $(u, v)$ in $G^c$ if and only if $(u, v) \notin E$, $G^c$ can be determined by checking all the pairs of vertices in $O(|V|^2)$ time. Therefore $f$ is computable in polynomial time.

2. If $G$ contains a clique $U \subseteq V$ of size $k$, then no pair of vertices in $U$ will be connected by an edge in $G^c$. Therefore $U$ is an IS of size $k$ for $G^c$.

3. If $G^c$ has an IS $U$ of size $k$, then any pair of distinct vertices in $U$ will be connected by an edge in $G$, therefore $U$ is a clique of size $k$ for $G$.

(b) Let DECIDE_IS($\langle G = (V, E), k \rangle$) be our (unlikely) $O(|V| + |E|)$ algorithm that decides IS. Based on DECIDE_IS, we can write the following recursive algorithm:

$$\text{MAX_SIZE}(\langle G = (V, E), i, j \rangle)$$

if $i = j$ then return $i$

middle $\leftarrow [(i + j)/2]$

if DECIDE_IS($\langle G = (V, E, middle) \rangle$)

then return $\text{MAX_SIZE}(\langle G = (V, E), middle, j \rangle)$

d else return $\text{MAX_SIZE}(\langle G = (V, E), i, middle - 1 \rangle)$
When we call \textsc{MaxSize}(\langle G = (V, E) \rangle, 1, |V|), we basically perform a binary search on all possible cardinalities of an independent set. The correctness of the algorithm follows from the observation that there is an independent set of size \( h \) iff the size of the maximum independent set is \( \geq h \). Therefore a binary search approach can be applied, yielding the desired running time of \( O((|V| + |E|) \log |V|) \).

\textbf{Exercise 7.15} A problem closely related to problem IS, defined in the previous exercise, is the following. Given an undirected graph \( G = (V, E) \), a \textit{maximal} independent set is an independent set \( S \) such that, for each \( v \in V - S \), \( S \cup \{v\} \) is not independent. That is, \( S \) cannot be “upgraded” to a larger independent set.

(a) Give an example of a graph where there is a \textit{maximal} independent set of size much smaller than the size of the \textit{maximum} independent set.

(b) Show that the problem of determining a maximal independent set can be solved in polynomial time.

\textbf{Answer:}

(a) Consider the following “star” graph:

Clearly, the node at the center of the star makes a \textit{maximal} independent set by itself, since all other nodes are connected to it. However, the \textit{maximum} independent set contains eight nodes. Note that the above example can be generalized to yield a discrepancy of \( \Theta(|V|) \) between the size of a \textit{a maximal} and a maximum independent set, for any value of \( |V| \).

(b) We build our maximal independent set \( S \) incrementally as follows. We start from the empty set and perform a linear scan the nodes. We add a new node \( v \) to \( S \) if \( S \cup \{v\} \) is still independent. The algorithm follows.
GREEDY_MAXIMAL_INDEPENDENT_SET(\(G = (V, E)\))

\(n \leftarrow |V|\)
\(S \leftarrow \emptyset\)

for \(i \leftarrow 1\) to \(n\) do
    \(indep \leftarrow \text{true}\)
    for each \(u \in \text{Adj}[v_i]\) do
        if \(u \in S\) then
            \(indep \leftarrow \text{false}\)
    if \(indep\) then
        \(S \leftarrow S \cup \{v_i\}\)

return \(S\)

The set \(S\) returned by the above algorithm is an independent set by construction. Let us now prove that \(S\) is maximal. Assume, for the sake of contradiction, that \(S\) is not maximal. Then, there is a node \(v_i \in V - S\) such that \(S \cup \{v_i\}\) is an independent set. Note that \(v_i\) was not added to \(S\), therefore, at the end of the \(i\)-th iteration of the outer loop, variable \(indep\) was \text{false}. This means that there was a node \(u \in S\) such that \(u \in \text{Adj}[v_i]\), which contradicts the hypothesis that \(S \cup \{v_i\}\) is an independent set.

Note that the outer loop is executed \(|V|\) times. During iteration \(i\), we execute the inner loop \(|\text{Adj}[v_i]|\) times, for a total of \(\Theta(|E|)\) iterations altogether. In each iteration, the check \(u \in S\) can be performed in \(O(\log |S|)\) time (using –say– a binary search tree to store \(S\)). Since \(|S| \leq |V|\), the running time of the above algorithm is then \(O(|V| + |E| \log |V|)\).

**Exercise 7.16** Given undirected graphs \(G_1 = (V(G_1), E(G_1))\) and \(G_2 = (V(G_2), E(G_2))\), we say that \(G_1\) is isomorphic to \(G_2\) if there is a one-to-one function \(\pi : V(G_1) \rightarrow V(G_2)\) such that \(\{u, v\} \in E(G_1)\) iff \(\{\pi(u), \pi(v)\} \in E(G_2)\). Consider the following decision problem:

**SI (SUBGRAPH ISOMORPHISM):**

**INSTANCE:** \(\langle G = (V(G), E(G)), H = (V(H), E(H)) \rangle\), with \(G\) and \(H\) undirected graphs

**QUESTION:** Does \(H\) contain a subgraph \(H' = (V(H'), E(H'))\), with \(V(H') \subseteq V(H)\) and \(E(H') \subseteq E(H)\) that is isomorphic to \(G\)?

Show that SI is NP-complete.

**Answer:** SI is clearly in \(NP\). Given a string \(x = \langle G, H \rangle \in \text{SI}\), a certificate \(y\) for SI is \(\langle H' = (V(H'), E(H'), \pi) \rangle\). Note that \(\pi\) can be represented as a sequence of \(|V(G)|\) pairs \((u, \pi(u))\), with \(u \in V(G)\), therefore the encoding of \(y\) is polynomial in the size of the
instance. On input \(\langle x, y \rangle\), the verifier first checks that the encodings for the instance and the certificate are well-formed, then checks that \(H'\) is indeed a subgraph of \(H\) with \(|V(G)|\) nodes, and finally checks that for any edge \((u, v)\) in \(E(G)\), edge \((\pi(u), \pi(v))\) is in \(E(H')\) and vice versa. These checks clearly take time polynomial in the size of \(\langle x, y \rangle\). The code of the algorithm is omitted for the sake of brevity.

In order to show that SI is \(NP\)-Hard, we show that CLIQUE \(\leq_P SI\). Recall that an instance of CLIQUE is \(\langle G, k \rangle\) and the question is whether \(G\) contains a complete subgraph of size \(k\). Let \(C_k\) be the graph \((\{1, 2, \ldots, k\}, \{\{u, v\} : 1 \leq u \neq v \leq k\})\), that is, \(C_k\) is the complete graph built on vertices \(V(C_k) = \{1, 2, \ldots, k\}\). Our reduction function is

\[
f(\langle G, k \rangle) = \langle C_k, G \rangle.
\]

Clearly, \(f\) is computable in polynomial time. To see that \(f\) reduces CLIQUE to SI, note that if \(G\) contains a complete subgraph with \(k\) nodes, then such subgraph is clearly isomorphic to \(C_k\) (all complete graphs with the same number of nodes are isomorphic). Vice versa, if \(G\) contains a subgraph isomorphic to \(C_k\), then such subgraph is itself a clique of \(k\) nodes (a complete graph can only be isomorphic to another complete graph). This suffices to show that CLIQUE \(\leq_P SI\), and the claim follows.

**Exercise 7.17** Consider the following decision problem:

**HS (Hitting Set):**

**INSTANCE:** \(\langle n, m, C_1, C_2, \ldots, C_m, k \rangle\), with \(C_i \subseteq \{1, 2, \ldots, n\}\) for \(1 \leq i \leq m\), and \(k \leq n\).

**QUESTION:** Is there a subset \(S' \subseteq \{1, 2, \ldots, n\}\) with \(|S'| = k\) and such that \(S' \cap C_i \neq \emptyset\), for \(1 \leq i \leq m\)?

Show that HS is \(NP\)-complete.

**Answer:** A candidate certificate for HS is a subset \(S' \subseteq \{1, 2, \ldots, n\}\). The verification algorithm first checks whether its first input \(x\) is a well-formed encoding \(x = \langle n, m, C_1, C_2, \ldots, C_m, k \rangle\) of an instance of HS; then checks that its second input encodes a subset of \(\{1, 2, \ldots, n\}\) of cardinality \(k\). If this is the case, the algorithm proceeds to check whether \(S' \cap C_i \neq \emptyset\), for \(1 \leq i \leq m\). Each such test can clearly be accomplished in polynomial time. Therefore HS is \(NP\).

In order to show that HS is \(NP\)-Hard, we exhibit a reduction from VERTEX COVER (VC) to HS. Recall that an instance of VC is \(\langle G = (V, E), k \rangle\) and the question is whether \(V\) contains a subset \(V'\) of size \(k\) such that each edge in \(E\) has at least one of its endpoints in \(V'\).
Let \( \pi : V \rightarrow \{1, 2, \ldots, |V|\} \) be an arbitrary one-to-one function from \( V \) to \( \{1, 2, \ldots, |V|\} \).
Our reduction function is the following:

\[
f((G = (V, E), k)) = (|V|, |E|, C_1, C_2, \ldots, C_{|E|}, k),
\]

where \( C_i = \{\pi(u), \pi(v)\} \) iff the \( i \)-th edge in \( E \) is \( \{u, v\} \).

Clearly, \( f \) is computable in polynomial time. To show that \( f \) reduces VC to HS, it is sufficient to observe that, by construction, \( G \) contains a vertex cover \( V' \) with \( k \) nodes if and only if \( \pi(V') \subseteq \{1, 2, \ldots, |V|\} \) has nonempty intersection with all the \( C_i \)'s. The proof follows since \( |\pi(V')| = |V'| = k \).

Exercise 7.18 Let \( L_1 \) and \( L_2 \) be two NP-Hard Languages, and assume that there exist a polynomial time reduction function \( f \) from SAT to \( L_1 \) with the further property that for any \( x \in \{0, 1\}^* \), \( f(x) \notin L_2 \). Show that \( L_1 \cup L_2 \) is also NP-Hard.

Answer: It is sufficient to prove that under the stated hypotheses, \( f \) also reduces SAT to \( L_1 \cup L_2 \). Indeed, if \( x \in \text{SAT} \), then \( f(x) \in L_1 \), since \( f \) reduces SAT to \( L_1 \), hence \( f(x) \in L_1 \cup L_2 \). Vice versa, if \( f(x) \in L_1 \cup L_2 \), it must be that \( f(x) \in L_1 \) (since \( f(x) \notin L_2 \) from the hypothesis), hence \( x \in \text{SAT} \) (again, since \( f \) reduces SAT to \( L_1 \)). Observe that the hypothesis \( L_2 \in \text{NPH} \) is not used in the above argument, hence the result holds regardless of the complexity of accepting language \( L_2 \).

Exercise 7.19 Consider the following decision problem:

**VERTEX COVER or INDEPENDENT SET (VCoIS):**

**INSTANCE:** \( \langle G = (V, E), h, k \rangle \), \( G \) undirected graph, \( 1 \leq h, k \leq |V| \).

**QUESTION:** Does \( G \) contain a vertex cover of size \( h \) or an independent set of size \( k \)?

Show that VCoIS is \( NP \)-Hard.

Answer: Consider the following straightforward reduction from VERTEX_COVER (V_C):

\[
f((G = (V, E), h)) = (G' = G, h, |V|).
\]

Clearly, \( f \) is computable in polynomial (in fact, linear) time. Let us now show that \( f \) is a valid reduction from VC to CoVC. If \( \langle G = (V, E), h \rangle \in \text{VC} \), then \( G \) has a vertex-cover \( \hat{V} \) of size \( h \). Since \( G' = G \) the same holds for \( G' \), hence \( \langle G' = G, h, |V| \rangle = f((G, h)) \in \text{CoVC} \). Viceversa, if \( \langle G, h \rangle \notin \text{VC} \), we first observe that \( E \) cannot be empty (since a graph made of
all isolated vertices admits vertex covers of any size). Clearly, \( G' = G \) does not have a vertex cover of size \( h \). Moreover, \( G' \) cannot have an independent set of size \( |V| \), since such a large independent set implies that \( E = \emptyset \). It follows that \( \langle G' = G, h, |V| \rangle = \not\in \text{CoVC} \). We have proved that \( f \) is a valid polynomial-time reduction from VC to VCoIS, hence the latter problem is NP-Hard.

\[ \square \]

**Exercise 7.20** Given an undirected graph \( G = (V, E) \), a dominating set \( D \subseteq V \) of \( G \) is a subset of vertices such that, for each nonisolated node \( v \in V \) (that is, each node \( v \) which is the endpoint of at least an edge), \( D \) contains \( v \) or one of its neighbors. Formally:

\[
\forall v \in V : v \text{ nonisolated } \Rightarrow (v \in D) \lor (\exists \{u, v\} \in E : u \in D).
\]

Consider the following decision problem:

**DOMINATING SET:**

**ISTANZA:** \( \langle G = (V, E), k \rangle \), \( k \leq |V| \)

**DOMANDA:** Is there a dominating set \( D \subseteq V \) with \( |D| = k \)?

We want to show that DOMINATING SET is NP-Hard. Consider the following reduction \( f \) from VERTEX COVER: given \( \langle G = (V, E), h \rangle \), for each edge \( \{u, v\} \in E \) add a new node \( z_{uv} \) and two new edges connecting \( z_{uv} \) to \( u \) and \( v \). Let also \( k = h \).

1. Show \( x \in \text{VERTEX COVER} \Rightarrow f(x) \in \text{DOMINATING SET} \).

2. Show \( f(x) \in \text{DOMINATING SET} \Rightarrow x \in \text{VERTEX COVER} \).

**Answer:** The suggested reduction is \( f(\langle G = (V, E), k \rangle) = \langle G' = (V', E'), h \rangle \), where

1. \( V' = V \cup \{z_{uv} : \{u, v\} \in E\} \). (For each edge \( \{u, v\} \in E \) we add a new node \( z_{uv} \) to \( V' \) ...)

2. \( E' = E \cup \{\{u, z_{uv}\}, \{v, z_{uv}\} : \{u, v\} \in E\} \). (... and connect \( z_{u,v} \) to \( u \) and \( v \) only.)

3. \( h = k \) (We look for a Dominating Set of \( G' \) as large as the Vertex Cover of \( G \)).

\( G' \) has \( |V| + |E| \) nodes and \( 3|E| \) edges, hence \( f \) can be computed in linear time in \( |\langle G = (V, E), k \rangle| \).

**Point 1** If \( x = \langle G = (V, E), k \rangle \in \text{VERTEX COVER} \), there exists a subset \( \hat{V} \subseteq V \) of size \( k \) such that each edge \( \{u, v\} \in E \) has at least one endpoint in \( \hat{V} \). We now show that \( \hat{V} \subseteq V' \) is also a dominating set of \( G' \). Consider any non-isolated node \( y \in V' \). If \( y \in V' \cap V \), then there exists an edge \( \{u, v\} \in E \). Since \( \hat{V} \) is a vertex-cover, either \( y \in \hat{V} \).
or $u \in \hat{V}$. If $y \not\in V' \cap V$, then there exists an edge $\{u, v\} \in E$ such that $y = z_{u,v}$, and $y$ has $u$ and $v$ as neighbors. Again, one of these latter two nodes must be in $\hat{V}$, since $\{u, v\} \in E$. The two cases together show that the dominating set condition holds for all non-isolated nodes, hence $\hat{V}$ is a dominating set in $G'$ of size $k$. Therefore $f(x) = \langle G' = (V', E'), k \rangle \in$ DOMINATING SET.

(Point 2) If $f(x) = \langle G' = (V', E'), k \rangle \in$ DOMINATING SET, there exists a dominating set $D \subseteq V'$ of size $k$. Observe that $D$ may contain nodes $z_{u,v} \not\in V$, so we cannot claim directly that $D$ is a vertex cover in $G$. However, we may substitute each node $z_{u,v} \in D$ with one of the two nodes $u$ or $v$ and still obtain a dominating set $D' \subseteq V$ of size at most $k$, since $z_{u,v}$ can only be used to dominate itself, $u$ or $v$, and the same task can be accomplished by either $u$ or $v$. Consider now an arbitrary $\{u, v\} \in E$. $D'$ must contain either $u$ or $v$ or otherwise the domination condition would not hold for $z_{u,v} \not\in D'$. Therefore $D'$ is a vertex cover for $G$ of size $\leq k$, which in turn implies that there is a vertex cover in $G$ of size $k$ (which can be obtained by adding $k - |D'|$ arbitrary nodes in $V$ to $D'$). Therefore $x = \langle G = (V, E), k \rangle \in$ VERTEX COVER.

Exercise 7.21 Given an undirected graph $G(V, E)$ with $|V| > 0$ even, and a subset $V' \subset V$, with $|V'| = |V|/2$, the edge set $B_G(V') = \{\{u, v\} \in E : (u \in V') \land (v \in V - V')\}$ is a cut called bisection of $G$ with respect to $V'$. Consider the following decision problems:

**MIN-BISECTION:**

I: $\langle G = (V, E), k \rangle$, $|V| > 0$ even, $0 \leq k \leq |V|^2/4$

D: $\exists V' \subset V, |V'| = |V|/2 : |B_G(V')| \leq k$?

**MAX-BISECTION:**

I: $\langle G = (V, E), k \rangle$, $|V| > 0$ even, $0 \leq k \leq |V|^2/4$

D: $\exists V' \subset V, |V'| = |V|/2 : |B_G(V')| \geq k$?

Show that MIN-BISECTION $\preceq_P$ MAX-BISECTION

**Answer:** Let $G = (V, E)$ be an undirected graph with $|V| > 0$ even, and let $V' \subset V$ with $|V'| = |V|/2$. It is immediate to argue that $B_{G^c}(V') = |V|^2/4 - B_G(V')$ since the set of all possible (undirected) edges between $V'$ and $V - V'$ contains exactly $|V|^2/4$ elements, and each such edge is either in $B_G(V')$ or in $B_{G^c}(V')$. Therefore $G$ has a bisection of size at most $k$ if and only if $G^c$ has a bisection of size at least $|V|^2/4 - k$. This proves that the function

$$f((G = (V, E), k)) = \langle G^c = (V, E^c), |V|^2/4 - k \rangle$$

which is clearly computable in polynomial (at most quadratic) time, reduces MIN-BISECTION to MAX-BISECTION. Observe that the same function also reduces MAX-BISECTION to
Exercise 7.22  Consider the following decision problem:

**NOT-ALL-EQUAL 4-CNF-SAT (NAE-4-CN-F-SAT):**

I: \( \langle \Phi(x_1, x_2, \ldots, x_n) = C_1 \land C_2 \land \cdots \land C_m \rangle, \Phi \text{ in 4-CN-F.} \)

D: Does there exist a truth assignment \( b \in \{0, 1\}^n \) under which each clause of \( \Phi \)
contains at least one true and one false literal?

Show that NAE-4-CN-F-SAT is NP-Hard.

**Answer:** Our reduction \( f \) is from 3-CN-F-SAT and is defined as follows. Let

\[ \Phi(x_1, \ldots, x_n) = C_1 \land \cdots \land C_m \]

be the 3-CN-F-SAT instance. Then

\[ f(\Phi) = \langle \Phi'(x_1, \ldots, x_n, x_{n+1}) = C'_1 \land C'_2 \land \cdots \land C'_m \rangle, \text{ with } C'_i = C_i \lor x_{n+1}, 1 \leq i \leq m. \]

Function \( f \) is clearly computable in polynomial (indeed, linear) time. Let us now show that \( f \) is a valid reduction. Assume that \( \Phi(x_1, \ldots, x_n) \in \text{3-CN-F-SAT} \). Then, there exists a truth assignment \( b \in \{0, 1\}^n \) which satisfies \( \Phi \). Since \( \Phi \) is a CNF formula, this implies that under \( b \) each clause contains a true literal. But then, under \( b' = (b|0) \), each clause in \( \Phi' \) has one true literal and one false one \((x_{n+1})\), hence \( f(\langle \Phi \rangle) = \Phi' \in \text{NAE-4-CN-F-SAT} \).

Vice versa, let \( \Phi' \in \text{NAE-4-CN-F-SAT} \), and let \( b' \) be the truth assignment under which each clause in \( \Phi' \) has one true literal and one false one. If \( b'_{n+1} = 0 \), then it must be that \( \Phi(b'_{1}, \ldots, b'_n) = 1 \), since each clause must also contain a true literal under \( b' \), hence \( \langle \Phi \rangle \in \text{3-CN-F-SAT} \). If \( b'_{n+1} = 1 \), then consider \( b'' = (\neg b'_{1}, \ldots, \neg b'_n, 0) \), and observe that under \( b'' \) each clause in \( \Phi' \) still has one false literal and one true literal (which must necessarily be one of the original literals of \( \Phi \)). Then again \( \Phi(b''_{1}, \ldots, b''_n) = 1 \), whence \( \langle \Phi \rangle \in \text{3-CN-F-SAT} \).

Exercise 7.23  Given a language \( L \in NP \), consider the following three cases.

(a) \( L = \Sigma^* \)

(b) \( L \neq \emptyset, \Sigma^* \) is accepted by a DFSA.

(c) \( L \) contains an \( NP \)-complete subset.

24
Under the assumption \( P \neq NP \), decide, for each of the above cases, whether 1) \( L \) is \( NP \)-complete or 2) \( L \) is not \( NP \)-complete or 3) \( L \) might be \( NP \)-complete or not. Redo the exercise under the assumption \( P = NP \).

**Exercise 7.24** Let \( L_1, L_2 \in \{0,1\}^* \). Under the assumption that \( P \neq NP \), prove or disprove the following propositions:

(a) \( L_1 \in P \Rightarrow L_1^c \in NP \).

(b) \( L_1 <_p L_2 \Leftrightarrow L_1^c <_p L_2^c \).

(c) \( L_1 <_p L_{SAT} \Rightarrow L_1 \in NPC \).

(d) \( L_1 <_p L_{SAT} \Rightarrow L_1 \in NP \).

(e) \( L_1 <_p L_2 \) and \( L_2 <_p L_1 \Rightarrow L_1, L_2 \in P \).

(f) A reduction function \( f \) is a one-to-one correspondence.

(g) If we restricted the input set of CLIQUE to graphs \( G = (V, E) \) of degree at most 7, then the resulting subproblem would be in \( P \).

(h) If there is an algorithm for CLIQUE with running time \( N^{O(\log N)} \), then every other problem in \( NP \) has an algorithm with a running time of the same form.

**Exercise 7.25** Consider the following decision problem:

BF\_SAT (BALANCED FORMULA SATISFIABILITY):

**INSTANCE:** \( \langle \Phi(x_1, x_2, \ldots, x_{2n}) \rangle \), \( \Phi \) is a boolean formula

**QUESTION:** Is there a satisfying assignment in which exactly \( n \) variables have value false?

Prove that BF\_SAT is \( NP \)-Complete.

**Exercise 7.26** Consider the following decision problem:

NCBF (NON CONSTANT BOOLEAN FORMULA):

**INSTANCE:** \( \langle \Phi(x_1, x_2, \ldots, x_n) \rangle \), \( \Phi \) is a boolean formula

**QUESTION:** Is \( \Phi(x_1, x_2, \ldots, x_n) \) a non constant function? (i.e., \( \Phi \neq false \) and \( \Phi \neq true \))

Show that NCBF is \( NP \)-Complete.
Exercise 7.27 Consider the following decision problem:

CoH (CLIQUE or HAMILTONIAN):

**INSTANCE:** \(G = (V, E), k\), with \(G\) an undirected graph and \(k > 0\)

**QUESTION:** Does \(G\) contain *either* a clique of size \(k\) *or* a hamiltonian circuit?

Show that CoH is \(NP\)-Complete.

Exercise 7.28 Consider the following decision problem:

RH (ROOT-HAMILTONIAN):

**INSTANCE:** \(G = (V, E)\), with \(G\) an undirected graph

**QUESTION:** Does \(G\) contain a simple cycle of length at least \(\lceil \sqrt{|V|} \rceil\)?

Show that RH is \(NP\)-Complete.

Exercise 7.29 Given an undirected graph \(G\), recall that a *hamiltonian path* is a simple path that touches all nodes of \(G\). Consider the following two problems:

HP (HAMILTONIAN PATH):

**INSTANCE:** \(G = (V, E)\), with \(G\) an undirected graph

**QUESTION:** Does \(G\) contain a hamiltonian path?

\(k\)-P (\(k\)-PATH):

**INSTANCE:** \(G, u, v, k\), with \(G = (V, E)\) an undirected graph, \(u \neq v \in V\) and \(k > 0\)

**QUESTION:** Does \(G\) contain a simple path containing at least \(k\) edges from \(u\) to \(v\)?

(a) Show that HP is \(NP\)-Complete.

(b) Show that \(k\)-P is \(NP\)-Complete.

(c) Show that HP and \(k\)-P are both in \(P\) when the graph \(G\) is restricted to be acyclic.
