

# Self-Assembling Sensor Networks

Christian Scheideler  
Dept. of Computer Science  
University of Paderborn

# Sensor Networks

# Sensor Networks

Our focus: self-assembling nano-sensors

## Why self-assembly?

- More flexible
- Easier to solve covering problems

# Sensor Networks

Our focus: self-assembling nano-sensors

Self-organizing nano-structures occur in many contexts

# Self-organizing Nano Structures

Nanotubes, crystals, DNA tiles,...

# Self-organizing Nano Structures

Bacterial colonies, mushrooms, corals,...

# Self-assembling Nano-Sensors

## Applications:

- Measure environmental conditions

# Self-assembling Nano-Sensors

## Applications:

- Measure structural conditions

# Self-assembling Nano-Sensors

## Applications:

- Monitor health and assist medical surgery

# Self-assembling Nano-Sensors

## Applications:

- Artificial skin or retina

# Self-assembling Nano-Sensors

**Basic approach:** nano-sensors can move and bond

## Cases:

- sensors are passive
- sensors are intelligent (finite automata)

# Self-assembling DNA Structures

Self-organizing, **passive** elements have been studied before in the context of self-assembling DNA structures.

# Modular Robotics

Self-organizing, **intelligent** elements have been studied before in modular robotics.

# Self-Assembling Nano-Sensors

## Basic problems:

- Sensors self-organize to form a predefined shape
- Sensors self-organize in order to coat a given surface

# Self-Assembling Nano-Sensors

Aggregation of information:

Via directed diffusion

Localization of events:

# Overview

## Passive nano-sensors:

- DNA self-assembly

## Intelligent nano-sensors:

- Finite automata and cellular automata
- Models for self-assembling nano-sensors
- Some problems and initial results

# DNA self-assembly

DNA self-assembly useful in two respects:

- Self-assembling nano-circuitry to establish a nano-sensor
- Self-assembling structures of nano-sensors

# DNA self-assembly

Basic building block: **Wang tile**.

- Every side has a color out of  $\Sigma$ .
- So a Wang tile is a tuple  $T \in \Sigma^4$ .

Two Wang tiles **bond** if their sides have the same color.

# DNA self-assembly

Two Wang tiles **bond** if their sides have the same color.

- Each bond color  $c$  has a **strength**  $s(c) \in \mathbb{N}$ .
- A tile is added to an assembly:  
summed strength of bonds  $\geq T$ .

# DNA self-assembly

**Problem:** What is the minimum number of tile types needed to form a  $n \times n$ -square for some temperature  $T$ ?

$T=1$ :

# DNA self-assembly

3x3-square:

**Question:** Is it possible to use less than  $n^2$  tile types for a  $n \times n$ -square?

# DNA self-assembly

No!

# DNA self-assembly

T=2:

-     : strength 2
-  : strength 1

# DNA self-assembly

$T=2$ , general construction:

$2n+1$  tile types  
are sufficient

# DNA self-assembly

Can we do better for  $T=2$ ?

Yes, we can with a binary counter approach.

Border squares of binary counter:

# DNA self-assembly

Border of binary counter:

Tiles for binary counter:

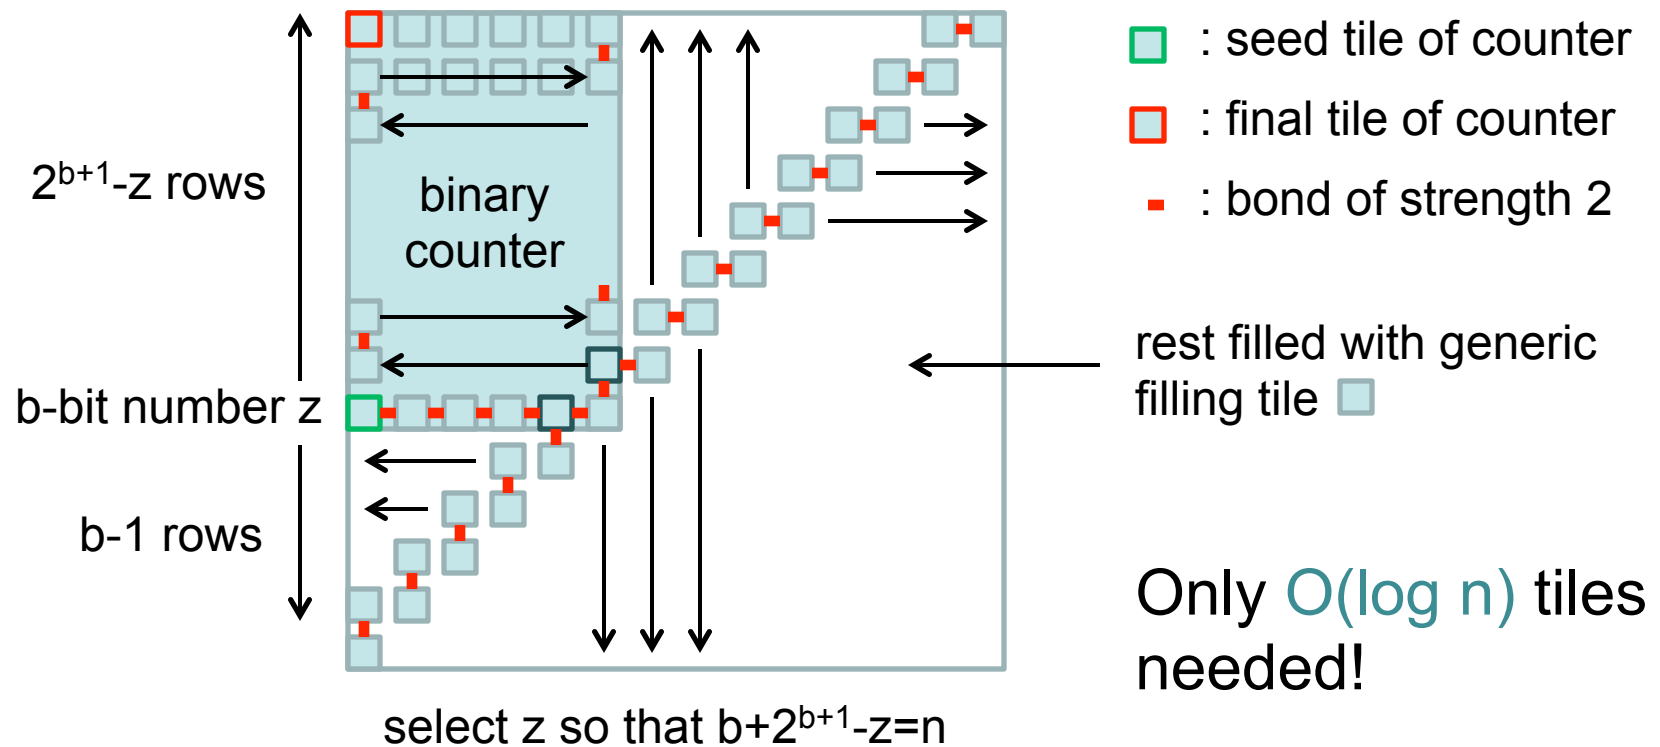

# DNA self-assembly

# DNA self-assembly

Strategy to construct  $n \times n$ -square:

# DNA self-assembly

One can do even better:

**Theorem:** For an infinite set of  $n$ -values, only  $f(n)$  tiles are needed to construct a  $n \times n$ -square, where  $f(n)$  can be an arbitrarily slow growing function.

**Theorem:** There is an infinite set of  $n$ -values that require  $\Omega(\log n / \log \log n)$  tiles to construct a  $n \times n$ -square.

**Proof:**  
after a few slides

For more details see:

P. Rothemund and E. Winfree

The program-size complexity of self-assembling squares  
In ACM STOC 2000.

# DNA self-assembly

Given a shape  $S$  let

- $T(S)$  be the minimum number of tiles needed to construct  $S$  and
- $K(S)$  be the size of the minimum program outputting  $S$  as a list of locations (also known as the Kolmogorov complexity of  $S$ )

**Theorem:** For any shape  $S$ ,

$$K(S) = \Theta(T(S) \log T(S))$$

**Proof:**

D. Soloveichik and E. Winfree  
Complexity of self-assembled shapes  
SIAM Journal on Computing 36(6), 2007.

# DNA self-assembly

## Kolmogorov complexity:

- Easier to understand for natural numbers.

**Theorem:** There are numbers  $n \in \mathbb{N}$  with Kolmogorov complexity  $\Omega(\log n)$ .

## Proof:

- Consider any  $k \in \mathbb{N}$ .
- There are  $2^k$  numbers that have a  $k$ -bit binary representation.
- Each of these numbers must have a unique smallest program to construct it.
- Therefore, each of these programs must have a unique binary representation.
- Hence, one of these numbers must have a program of size  $\Omega(\log n)$ .

**Note:** most of prime numbers have Kolmogorov complexity  $o(\log n)$ .

# DNA self-assembly

What is the Kolmogorov complexity of a  $n \times n$ -square?

- From the previous theorem, there must be a  $n \times n$ -square with Kolmogorov complexity  $\Omega(\log n)$ .
- Hence, it follows from  $K(S) = \Theta(T(S) \log T(S))$  that there are  $n \times n$ -squares that require  $\Omega(\log n / \log \log n)$  tiles, which confirms our previous lower bound.

# DNA self-assembly

How to design tiles for arbitrary shapes?

**Definition:** An **irreducible** shape is a shape in which we cannot shrink  $k \times k$ -slots to  $1 \times 1$ -slots without changing the shape.

**Examples:**

Irreducible shape:

Reducible shape:

# DNA self-assembly

How to design tiles for arbitrary shapes?

**Definition:** An **irreducible** shape is a shape in which we cannot shrink  $k \times k$ -slots to  $1 \times 1$ -slots without changing the shape.

**Examples:**

Reducible shapes:

# DNA self-assembly

## Irreducible shape:

- Each slot gets its own tile type.
- The tiles form a spanning tree of the shape.

# DNA self-assembly

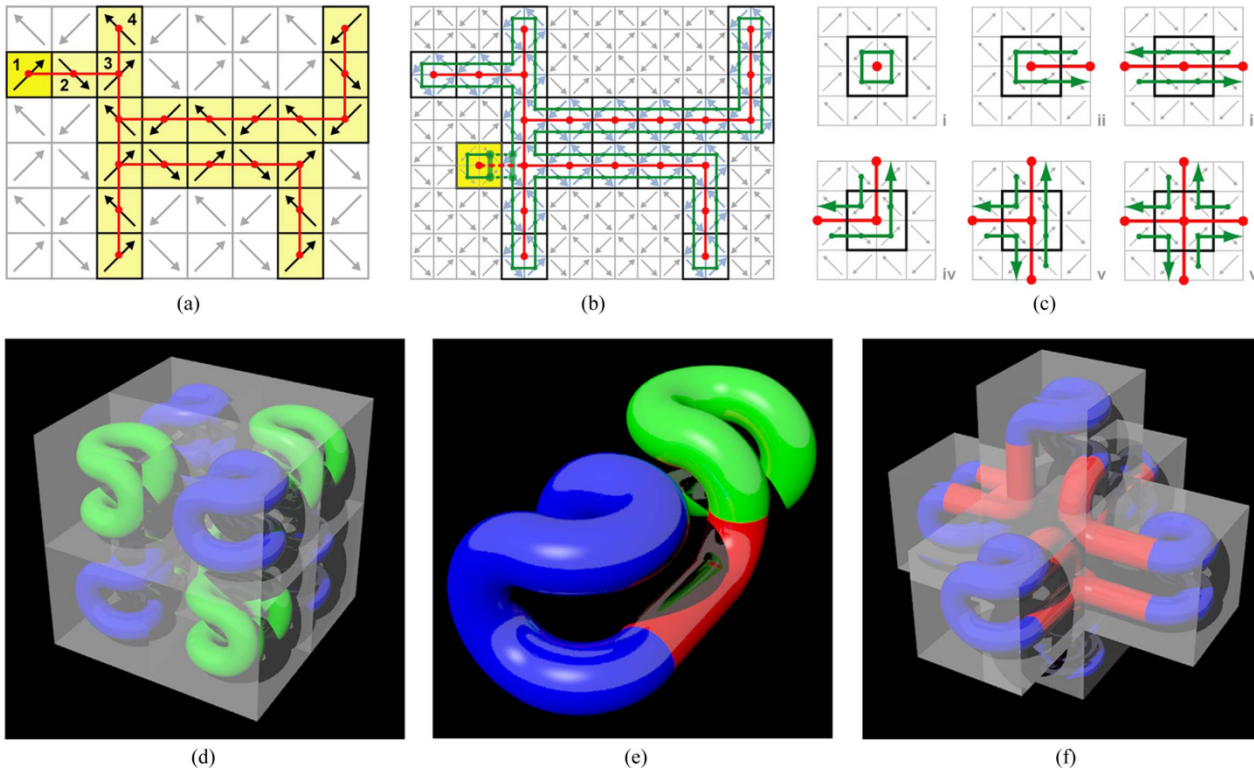

## Reducible shape $S$ :

- Determine the unique  $k$  that shrinks  $S$  to an irreducible shape  $S'$ .
- Construct a tile system  $T'$  for  $S'$ .
- Construct a tile system  $T$  for  $S$  so that for each tile  $T'_i \in T'$ , a  $k \times k$ -square  $B_i$  is built.

# DNA self-assembly

## Alternative approach: foldable strings

# DNA self-assembly

## Basic approach:

- Consider any shape  $S$ .
- Determine the unique  $k$  that shrinks  $S$  to an irreducible shape  $S'$ .
- Construct a (foldable) string  $L'$  for  $S'$ .
- Extend every unit in  $L'$  by a foldable substring folding into a  $k \times k$ -square.

# Overview

## Passive nano-sensors:

- DNA self-assembly

## Intelligent nano-sensors:

- Finite automata and cellular automata
- Models for self-assembling nano-sensors
- Some problems and initial results

# Finite Automaton

A **finite automaton**  $M$  is a tuple  $M=(Q, \Sigma, \delta, q_0, F)$  where

- $Q$  is a finite set of states
- $\Sigma$  is the input alphabet
- $\delta:Q \times \Sigma \rightarrow Q$  is the transition function
- $q_0 \in Q$  is the initial state
- $F \subseteq Q$  is the set of final states

Example:

- $Q=\{q_0, q_1\}$
- $\Sigma=\{0, 1\}$
- $F=\{q_1\}$

# Finite Automaton

A **finite automaton**  $M$  is a tuple  $M=(Q, \Sigma, \delta, q_0, F)$  where

- $Q$  is a finite set of states
- $\Sigma$  is the input alphabet
- $\delta:Q \times \Sigma \rightarrow Q$  is the transition function
- $q_0 \in Q$  is the initial state
- $F \subseteq Q$  is the set of final states

## Advantage:

- easy to build

## Disadvantage:

- very limited computational capabilities (regular languages)

# Cellular Automaton

A **cellular automaton**  $C=(Q,\delta)$  is a finite automaton that determines the behavior of any cell in a grid.

Examples of grids:

# Cellular Automaton

A **cellular automaton**  $C=(Q,\delta)$  is a finite automaton that determines the behavior of any cell in a grid.

$C$  takes its own state and all 8 neighboring states into account:  $\delta:Q^9\rightarrow Q$

# Cellular Automaton

A **cellular automaton**  $C=(Q,\delta)$  is a finite automaton that determines the behavior of any cell in a grid.

Standard assumption:

Cells act in a perfectly **synchronized** way, i.e., the system operates in discrete time steps  $t$

# Cellular Automaton

**Theorem:** On an infinite grid, a cellular automaton can emulate any Turing machine algorithm.

**Turing machine:**

$\delta: Q \times \Sigma \rightarrow Q \times \{L, N, R\}$ , i.e., a TM can move one cell to left or right in each step

# Cellular Automaton

**Theorem:** On an infinite grid, a cellular automaton can emulate any Turing machine algorithm.

Cellular automaton:

# Cellular Automaton

Are cellular automata an appropriate model for self-assembling nano-sensors?

## Rule:

- Each nano-sensor (**particle**) can observe its direct neighborhood and decide based on that where to move next

New position needs to know 2-neighborhood to decide that!

# Cellular Automaton

Are cellular automata an appropriate model for self-assembling nano-sensors?

- On the other hand, a cellular automaton can do many things a particle is not allowed to do

# Particle Model

Better: separate particle model

- A particle is a finite automaton of the form  $P=(Q,\delta)$  where  $\delta:Q^9 \rightarrow Q \times \{0,\dots,8\}$

- A particle can only move to an **empty** spot (otherwise **difficult** to backoff as previous position might get occupied by another particle).

# Particle Model

Better: separate particle model

- A particle is a finite automaton of the form  $P=(Q,\delta)$  where  $\delta:Q^9 \rightarrow Q \times \{0,\dots,8\}$

- If two particles collide, they backoff to their previous spot.

# Particle Model

## Technical problems:

- How can a particle interact with all 8 neighboring particles?
- How can two diagonally moving particles pass each other?

# Particle Model

## Technical problems:

- How does a particle move around the corner?
- How can particles move while preserving connectivity?

# Particle Model

## Technical problems:

- Are diagonal connections sufficient for connectivity?
- We will see that deterministic particles can run into problems.

How to realize randomization?

# Particle Model

## Algorithmic problems:

- How can a particle find out whether its movement would disconnect the structure?

# Particle Model

## Algorithmic problems:

- Even if the particles had connectivity information, how can joint movements be coordinated?

→ also randomization needed to break symmetry!

# Particle Model

How about a different grid:

A particle is a finite automaton of the form

$P=(Q,\delta)$  with  
 $\delta:Q^7\rightarrow Q\times\{0,\dots,6\}$

# Particle Model

Movement of a particle:

A particle expands and contracts.

# Particle Model

This also allows handover of slot without running into backoff problems.

# Particle Model

## Technical problems:

- How can a particle interact with all neighboring particles?

- How can two diagonally moving particles pass each other?

# Particle Model

## Technical problems:

- How does a particle move around the corner?

- How can particles move while preserving connectivity?

# Particle Model

## Technical problems:

- Are diagonal connections sufficient for connectivity?

- Deterministic particles may still run into problems.  
**How to realize randomization?**

# Particle Model

## Algorithmic problems:

- How can a particle find out whether its movement would disconnect the structure?

Still a hard problem...

# Self-Assembling Nano-Sensors

## Basic problems:

- Sensors self-organize to form a predefined shape
- Sensors self-organize in order to coat a given surface

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

Consider the problem of covering a surface.

# Covering Problem

**Additional rule:** every particle that is not in contact with surface moves to left.

# Covering Problem

**Infinite surface:** eventually, just one thin layer of particles.

# Covering Problem

**Infinite surface:** eventually, just one thin layer of particles.

# Predefined Shape

**Problem:** Given a predefined shape and a connected set of particles, form the largest possible structure of that shape with these particles.

# Predefined Shape

**Idea:** use solution to covering problem to establish predefined shape

Add layer by layer  
to seed structure

# Predefined Shape

**Idea:** use solution to covering problem to establish predefined shape

# Predefined Shape

# Predefined Shape

More complex **convex** shapes:

- Start with irreducible structure
- Grow from there layer by layer

**Nonconvex** shapes:

- Still unclear how to do that

# Self-assembling Nano-Sensors
